The death of Dr KEPPEL BARRETT on April 21 has caused sincere grief in many homes in Kensington, where he practised for over forty years. Born at Grimstone in Norfolk, Alfred Keppel Barrett was the eldest son of the late Dr A E Barrett and grandson of the late Rev the Hon Thomas Robert Keppel. He was a student of St Mary's Hospital, Paddington, and qualified MRCS L R C P in 1891, a few years later succeeding to his father's practice. Dr Barrett served on numerous committees and was a member of many societies, including the West London Medico-Chirurgical Society, the Society of Apothecaries, and was a Fellow of the Hunterian Society and secretary of the Kensington Branch of the Royal Medical Benevolent Fund. For many years he was a member of the Executive Committee of the Kensington Division of the British Medical Association and of the London Panel Committee. He was also treasurer of the Society of Members of the Royal College of Surgeons of England. He leaves a widow and five daughters, to whom the sincere sympathy of their numerous friends is extended. His loss will be greatly felt in Kensington, where his devotion to duty and genuine kindness to all in trouble endeared him to a large circle of friends and patients who will not easily forget him. The funeral service took place at St Mary Abbots Church, which was very full, the congregation including a large number of medical men.

SIR MAURICE ABBOT-ANDERSON died at his home at Bath on May 3 after a short illness. The son of Major General Abbot-Anderson, he was born in 1861 and studied medicine at University College, London, and at Newcastle-on-Tyne, graduating MB, BS of Durham University in 1886 and taking the MRCS a year later. He was then in turn house-physician at University College Hospital and house surgeon at the Salop Infirmary. Settling in general practice he was appointed many years ago physician to the late Princess Royal (Duchess of Fife) and her household. When she and her husband were shipwrecked in the liner *Delhi* in 1911 Abbot-Anderson went to Egypt to attend them, but the Duke of Fife died before his arrival. Abbot-Anderson was for some years honorary surgeon to the Farringdon General Dispensary and Lying-in Hospital and honorary medical officer to the Housing Association for Officers' Families. For his services to the Duchess of Fife he was made MVO in 1908 and received a knighthood in 1912; he was advanced to CVO in 1921. At retirement he devoted much attention to organizations concerned with the preservation of the countryside and ancient national possessions in England, Scotland, and Wales. He was a member of the National Trust, and founded Flora's League for the protection of wild flowers, ferns, and trees.

Dr FREDERIC JAY COTTON, orthopaedic surgeon and founder and regent of the board of governors of the American College of Surgeons, died of a heart attack in Boston on April 14, aged 68.

Dr WILLIAM FRANKLIN ELGIN, associate of the late Major Walter Reed at the old Marine Hospital, Washington, and pioneer in vaccine development, died in Philadelphia on April 18 aged 76.

## Universities and Colleges

## UNIVERSITY OF LONDON

The following appointments to the Senate for the period 1953-54 are announced: Faculty of Medicine: Mr W. Gurling, Ball F.R.C.S., and Dr A. M. H. Gray (reappointed); General Medical Schools: Professor I. S. Dudgeon (reappointed).

A course of three lectures on 'Variation in the Response to Analgesic Drugs' will be given at the Wellcome Institute for Medical Research, Euston Road, N.W. by Dr J. W. Trevin on May 23, 24 and 25 at 5.30 p.m. At the first lecture the chair will be taken by Sir Henry Dale, F.R.S.

Two special University lectures in anthropology entitled *Sinanthropus Pekinensis* and his Significance for the Problem of Human Evolution and *Sinanthropus Pekinensis* in Comparison with Other Fossil Hominids will be given at University College Gower Street W.C. by Dr. I. Weidenreich, Visiting Professor of Anatomy, Peking Union Medical College and Director of the Cenozoic Research Laboratory, Peking, on May 20 and June 1 at 5.15 pm.

All the above lectures which will be illustrated with lantern slides are addressed to students of the University and to others interested in the subject. Admission is free without ticket.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

At the meeting of the College held on April 28 licenses to practise physic were conferred upon the following 194 candidates (including sixteen women) who had passed the final examination in Medicine, Surgery and Midwifery of the Conjoint Board and have complied with the necessary by laws.

Diplomas in Child Health were granted jointly with the Royal College of Surgeons of England to the twenty-three candidates whose names were printed in the report of the meeting of the Council of the Royal College of Surgeons of England in the *Journal* of April 23 (p. 929).

## Medical Notes in Parliament

The House of Commons this week discussed the Air Estimates and the increase of British air armaments. Progress was made with the Housing (Rural Workers) Amendment Bill, the Administration of Justice (Miscellaneous Provisions) Bill, and other measures.

### Progress of Bills

In the House of Lords on May 10 the Prevention and Treatment of Blindness (Scotland) Bill and the Hire Purchase Bill were brought from the Commons and read a first time. The Increase of Rent and Mortgage Interest (Restrictions) Bill passed through committee.

The Earl of Onslow presided at a meeting of the Joint Committee of both Houses of Parliament on the Food and Drugs Bill in the House of Lords on May 10. Among the clauses considered were those dealing with the sale of our food and the control and licensing of laundries. The Committee adjourned until May 11. Sir Francis Fremantle is a member of this Joint Committee.

The Bakehouses Bill was reported with amendments from a Standing Committee of the House of Commons on May 2. Its title has been changed to the Baking Industry (Hours of Work) Bill.

The Hire Purchase Bill was read a third time in the House of Commons on May 6.

The Eire (Confirmation of Agreements) Bill was read a second time in the House of Commons on May 3.

In the House of Commons on May 10 Mr Foot presented the Local Authorities and Local Government Officers (Joint Council) Bill which makes provision for the constitution of joint councils of representatives of local authorities and officers and servants of such authorities.

### Cost of School Health Services

On May 2 Mr T. MORRIS asked the Parliamentary Secretary to the Board of Education the total of the grants paid by the Board to local education authorities and voluntary institutions in respect of health services for school children. Mr KENNETH LINDSAY said the special services for elementary school children included medical inspection and treatment, special schools, organization of physical training, play centres, nursery schools and provision of meals. On the basis of the provisional figures for 1936-7 forwarded by local education authorities the grant payable to these for that year—50 per cent of their expenditure—was approximately £2,668,000 in respect of these special services. Grants to voluntary bodies for special schools, play centres and nursery schools in 1936-7 amounted to £55,136.

## Extension of Medical Benefits

On May 3 Mr D ADAMS asked whether the Government was considering measures financial or administrative to extend the scope of medical benefits to include consultant specialist and pathological services so that a more fundamental attack on health problems might be made. Mr BERNAYS said that important matters of finance and administration were involved.

and the Minister could not undertake to make any pronouncement on the subject which would have to be considered at the proper time in relation to the general financial resources of the country.

Mr ADAMS asked whether in view of the admitted necessity for further action on the lines of the question, the Parliamentary Secretary intended to give it further consideration. Mr BERNAYS said that the question was largely concerned with insured persons and was largely a matter of accommodation in hospitals set up for special diagnosis and treatment of disease under the Local Government Act, 1929. The number of those hospitals was steadily increasing.

#### Rheumatism Facilities for Treatment

On May 3 Mr D ADAMS asked what State facilities were provided for the treatment of rheumatism, and what extensions of these facilities were being considered. Mr BERNAYS replied that facilities for the treatment of this group of diseases were provided by most general hospitals and by a number of specialized voluntary institutions. Local authorities were increasingly making provision for the treatment of acute rheumatism in children. The medical advisers of the Ministry of Health were in close co-operation with the bodies concerned with combating and with research into rheumatic diseases. Mr DE LA BERE asked if the Minister had ever heard of the Droitwich Spa treatment.

#### Hospital Trust Deeds and Taxation

When Budget resolutions were debated on report on May 4 the House of Commons agreed without debate to the resolution increasing the standard rate of income tax to 5s 6d in the £. Subsequent resolutions were discussed and approved. In a discussion on the provisions of the Budget as regards settlements Mr BENSON said scarcely an institution which depended on public subscriptions but printed seven-year trust documents and distributed them broadcast. If a surtax payer giving a full rate made an annual donation of £100 to some institution under one of these seven-year trusts it cost the Government £70 a year and the donor £30. Why should the Chancellor of the Exchequer be compelled to subscribe to any particular institution or charity?

Sir TERENCE O'CONNOR, the Solicitor General, said Mr BENSON's suggestion would spread alarm and despondency among charitable institutions in this country. The root of the present law was that charities were treated as an exception and were exempted from the ordinary provisions of the Income Tax Acts. They were entitled to ask that taxes which had been paid on such incomes should be paid back. Anything which would vary that position would not be acceptable. Sir Terence said Mr BENSON had complained that he could not understand why a man should be entitled to make a settlement under which he undertook to pay to a particular hospital a sum of money over a series of years and why the hospital should be entitled to claim back the income tax which had been deducted. Sir Terence contended that it would be disastrous to charities if Parliament now altered the favoured position which they enjoyed.

The House approved the resolution dealing with settlements. An amendment tabled by Mr BENSON which specified hospitals was not called. Other resolutions were also approved, and the Finance Bill based upon the Budget resolutions, was brought in and read a first time.

#### Prevention and Treatment of Blindness in Scotland

The Prevention and Treatment of Blindness (Scotland) Bill passed through report and third reading in the House of Commons on May 6. During the report stage an amendment was inserted to ensure that any scheme prepared by a local authority under the Bill must be subject to the sanction of the Department of Health for Scotland. Mr ALLAN CHAPMAN and Mr GARRO JONES, in moving and seconding this amendment explained that it was to limit the provision of the Bill entitling local authorities to take such measures as they thought would assist in the prevention of blindness. Mr Garro Jones said some local authorities acting in advance of the Statute, had

interpreted the provisions of this Bill as much wider than were intended, and had invested themselves with power to bring pressure upon blind persons to prevent their marriage, if the medical officer of health thought that such a marriage would be undesirable.

#### Rural Housing Improvements

In the House of Commons on May 9 Sir KINGSLEY WOOD moved the second reading of the Housing (Rural Workers) Amendment Bill, which, he said, extended the operation of the original Acts for four years, up to September 30, 1942. Experience gained in administering the Acts showed that houses of good quality were being provided. In communicating with the local authorities he would ask district councils to ascertain themselves what cottages needed reconditioning and where the owners were unwilling to do the work, to consider exercising their powers to buy the cottages and themselves recondition them. Where the county council was the authority lists of cottages requiring reconditioning would be sent to it.

Mr GREENWOOD urged that there should be guarantees for the improvement of administration. Something should be done to establish proper standards of accommodation and amenities.

Sir FRANCIS FREMANTLE said that the Bill was a small measure but should not be belittled for that reason. It meant everything to the tenants of the houses concerned. There was a danger that local authorities, not understanding their responsibilities, might make grants for keeping alive and reconditioning houses which were not worthy to be reconditioned. He spoke very strongly on that point as an old county medical officer of health. Rural housing was one of the subjects on which medical officers of health were very keen. The county medical officers of health through their association, were very much in favour of the rural housing Acts and of the Bill but they were anxious that much more control should be exercised. The medical officer of health for Devon had given the association a good account of the working of the Acts in his county, and the association would like to see this state of affairs spread to other counties. There were many good houses built in the middle of the last century which were quite capable of being improved.

The Bill was read a second time.

#### The BMA and the Matrimonial Causes Act

In the House of Commons on May 9 Sir DONALD SOMERVILLE moved the second reading of the Administration of Justice (Miscellaneous Provisions) Bill, which has passed the House of Lords. During the discussion Mr A. P. HERBERT mentioned two points arising under the administration of the Matrimonial Causes Act, which Parliament passed last year and in regard to which people, he said, complained that certain respects the intentions of Parliament were not being carried out. The first point was with regard to the provision which gave a right to sue for a dissolution of marriage when the co-respondent had been of unsound mind for five years. During the debates on the Act last year a great deal was heard from doctors about the possibility or doubtfulness of a doctor being able to say in every case that a person was incurably insane, but now the British Medical Association, in a recent report, had raised two new points. The *British Medical Journal* stated:

The Council has considered the ethical position of a medical man in charge of an insane patient when approached for an opinion by a prospective petitioner and the position of the medical man in the event of a patient recovering. The Council is advised that any opinion given by the medical practitioner as to the patient being of unsound mind would not be covered by the protection given by the Mental Treatment Act or the Lunacy Act. The Council would be for the practitioner to decline to express an opinion save by the direction of the court, but that he should place his records of the case at the disposal of an independent medical expert nominated by the petitioner. As to the ethical aspect of the problem the Council considered that the medical man responsible for the care of the patient was

be justified in giving an opinion except at the express direction of the court. The adoption of this attitude would however make the Act unworkable and the Council feels that the most satisfactory way out of the difficulty would be the introduction of an enabling legislation.

He (Mr Herbert) would not go further into the matter. He was not trying to raise any controversial point. He was merely suggesting, that it might be that the intentions of the Act were not being carried out and if there was any way by which this matter could be put right he would be glad.

The other point was that there were many cases in which the husband or wife had been deserted and when the case came before the court they found that through the fault of the magistrate some years ago—not through any fault of Parliament—who quite unnecessarily and wrongly introduced in the separation order what was called a non-cohabitation clause, they were not entitled to divorce. He suggested that the Law Officers should consider the question.

The Bill was read a second time.

**Birmingham Merit Home Inmate Attacks 1.**—Mr RHYNS DAVIES asked on May 5 whether the attention of the Minister of Health had been drawn to the case of a Birmingham mental home in which two drunken attendants were hired for attacking and beating an inmate while a third stood by and encouraged them, and whether he would call for a report on the conduct of that institution. Sir KINGSLEY WOOD replied that his attention had been drawn to this case and the prosecution was instituted at the instance of the Board of Control, the person in question having previously been instantly dismissed. He had before him a report made by two Commissioners of the Board who inspected the institution on March 23 and 24. They reported favourably upon its administration and upon the care and treatment of the patients.

**British Spas and Publicity.**—In an answer on May 5 to Mr Ivor Guest Sir KINGSLEY WOOD said opportunity had been taken in the annual report of the Chief Medical Officer of the Department for the year 1935 to draw attention to the excellent work of British spa hospitals and to the value of British spas. The British Spas Federation working in co-operation with the Travel and Industrial Development Association of Great Britain and Ireland which had been approved by him under the Local Authorities (Publicity) Act 1931 was making every effort to popularize British spas at home and abroad.

**Diphtheria Mortality.**—On May 5 Sir KINGSLEY WOOD furnished Sir Arnold Wilson with the following figures of the deaths from diphtheria of children under 15 in England and Wales in 1933 there were 2,487 deaths, 1934 3,826, 1935 3,256 and 1936 2,884.

#### Notes in Brief

Sir Samuel Hoare hopes immediately before or after the Whitsuntide recess to introduce legislation to cover young persons employed in unregulated occupations.

In 1937 the Stoke Panel of the Silicosis Medical Board granted on applications from the pottery industry (practically all from North Staffordshire) 42 death certificates and refused 6. It granted in the same year 38 disablement certificates and refused 47. For the year 1936 the comparable figures were 42, 6, 38, 47.

When an opportunity occurs for amending legislation Sir Samuel Hoare will consider whether the period of one year after a worker has ceased to be employed in a lead process should be extended to five years as that within which a claim for compensation can be made.

The Interdepartmental Committee on Nursing Services has in mind that it may be desirable to issue an interim report.

No cases of small pox have been reported recently amongst British troops in Hong Kong.

The English-speaking medical unit in China has set up its headquarters at Changsha and is working in close contact with the Chinese Government health administration.

## Medical News

The King has approved the recommendation of the Home Secretary that from June 1 Dr J. C. W. Methven be appointed one of H.M. Commissioners of Prisons in the place of Dr W. Norwood East who will retire on that date.

Dr Percy Stocks will read a paper on 'The Effects of Occupation and of its Accompanying Environment on Mortality' before the Royal Statistical Society at the Royal Society of Art, John Street, Adelphi W.C. on Tuesday May 17 at 5.15 p.m.

A meeting of the Medico-Legal Society will be held at 26 Portland Place W. on Thursday May 26 at 8.30 p.m. when an address will be given by Dr L. A. Weatherly on 'Debatable Medico-Legal Episodes in my Days Before Yesterday'.

The next quarterly meeting of the Royal Medico-Psychological Association will be held at 11 Chandos Street W. on Friday May 20 at 2.0 p.m. when papers will be read on 'The Alleged Inadequacy in Numbers of Medical Officers in Mental Hospital'. A discussion will follow.

The thirty-ninth annual meeting of the Lebanon Hospital for Mental Diseases will be held at the Cornhill Upper Woburn Place W.C. on Tuesday May 17 at 4 p.m. The speakers include the President (Dr Percy Smith), Sir Hubert Bond M.D. Senior Commissioner of the Board of Control and Dr Serin (Paris).

On Thursday May 19 at 7.30 p.m. a conference will be held at the Caxton Hall S.W.1 to inaugurate the work of the Marriage Guidance Committee. This is a voluntary body which has been established for the purpose of providing practical help and advice on problems connected with marriage and the family. The conference will be attended by representatives of different professions and medical practitioners who are interested in the subject or preparation for marriage are invited to be present. The secretary of the committee is Mrs M. C. Hume, 13 Wildwood Road N.W.11.

The Swiss Society of Surgery will hold its twenty-fifth annual meeting from May 20 to 22 at Berne under the presidency of Professor Q. Jentzer of Geneva. The chief subject for discussion will be neurosurgery. Further information can be obtained from Professor F. Merke, Medizinische Facultät Basle.

We are informed that the clinical meeting of the Society of Radiotherapists which was to have been held at the rooms of the Medical Society of London is now to be held at the Middlesex Hospital. There is no change in the date (Friday May 20 at 5 p.m.).

The Medical Research Council has appointed Dr Karl Stern to the Kathleen Schlesinger Research Fellowship for the year 1938-9. The Fellowship is provided from a fund established by the late Mr Eugen M. Schlesinger and Mrs Schlesinger in memory of their daughter. It is given for investigations of cysts of the brain or allied conditions and is ordinarily tenable at the National Hospital for Diseases of the Nervous System, Queen Square, London.

Queen Mary opened the new out-patient department of the Midway Mission Hospital, Bethnal Green E. on May 6 and afterwards inspected the hospital.

A bronze bust of the late Sir Gratton Elliot Smith by Mr A. H. Gerrard was unveiled on May 4 in the Thane Library in the medical science building at University College, London.

On April 24 the seventieth anniversary of her birth, a monument to Mme Curie was unveiled in Roosevelt Park, Raritan Township, New Jersey, U.S.A.

A tour will be organized at Whitsuntide by the Societe Medicaire du Littoral Mediterranee from June 2 to 10 visiting Nice, Cannes, Peiracava, Roquebrune, Ajaccio, Bastia and Turin. Scientific meetings and demonstrations will be held in various places. Full details may be obtained from the Secretary of the Society, Rue Verdi 24, Nice.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended April 30, 1938

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland Median values for the last 9 years for (a) and (b)

Figures of Births and Deaths and of Deaths recorded under each infectious disease, are for (a) The 126 great towns (123 in 1937) in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns (9 in 1937) in Northern Ireland

A dash — denotes no cases, a blank space denotes disease not notifiable or no return available

Disease	1938					1937 (Corresponding Week)					1929-37 (Median Value Corresponding Weeks)

† As reported last year.  
\* For Oct. 1-1937 puerperal fever was made notifiable only in the administrative county of London.

‡ Includes primary form in figures for England and Wales (administrative county) and Northern Ireland.

## EPIDEMIOLOGICAL NOTES

## Enteric Fever

Notifications of enteric fever in England and Wales have dropped from 21 in the previous week to 20 in the week under review of these there was 1 case in the county of London. During the week under review 1 case of paratyphoid fever was reported at Cardiff and the outbreak appears to be under control. Of the 7 cases notified in Scotland 4 were of typhoid fever in Glasgow and 1 in Perth and Kinross county the remaining 2 cases notified were 1 of paratyphoid fever in Ross and Cromarty belonging to the outbreak reported in these columns last week and 1 of paratyphoid fever notified in Roxburgh county but it has since been shown that this case notified as paratyphoid was in fact the first case of an outbreak of typhoid fever involving 75 cases at the time of going to press—53 in Hawick and the remaining 2 (1 each from Riccarton and Newcastleton) in the southern part of the county. The case at Newcastleton is a boy of 13 years who goes to school at Hawick. So far the source of the infection has not been ascertained.

## Diphtheria and Scarlet Fever

The notifications of diphtheria remained about the same as in the previous week in England and Wales and Northern Ireland while they showed an increase in Scotland and a decrease in Eire. In London a decided drop was observed. Compared with the median value for the corresponding week in the last nine years there was a marked decrease in the figures for London while for England and Wales there has been an increase. Notifications of scarlet fever for England and Wales showed an increase over those of the previous week and both are considerably in excess of the median value for the last nine years. A slight increase has been noted in London but the figures remain well below the median value. In Scotland and Eire decreases were noted while in Northern Ireland there was a slight increase.

## Primary and Influenzal Pneumonia

During the two previous weeks and the week under review the deaths from influenza in England and Wales have been 52, 56, and 63 respectively and the figures in London 4, 6 and 8 respectively. A considerable increase in the notifications of primary and influenzal pneumonia has been observed in England and Wales the figures for the last three weeks being 847, 1,212, 1,270 (week under review) respectively while in London the numbers have remained almost stationary—70, 79 and 72 respectively. As the Registrar General's returns do not differentiate between primary and influenzal pneumonia it is not possible to state which is responsible for the increase. The rise in the number of deaths from influenza suggests that it is on the increase and we are informed that there has been a rise in the incidence of primary pneumonia, particularly in Yorkshire. The increase in England and Wales is due mainly to local outbreaks in the Midlands and the West Riding (Yorks). During the week under review there were 115 notifications of pneumonia in Warwickshire of which 91 were in Birmingham and in the West Riding there were 165 notifications of which 56 were in Sheffield and 35 in Leeds. In Scotland there has been no increase in influenzal pneumonia, but a pronounced rise in the notifications of primary pneumonia the figures for the last three weeks being 191, 213 and 275 (week under review) respectively.

## Measles

In the 126 Great Towns in England and Wales there were 35 deaths from measles, compared with 40 in the previous week of these 7 (4) occurred in London 3 (4) in Kingston upon Hull and 2 each in Croydon (0) Leyton

(0) Sheffield (0) and Plymouth (2). The figures in parentheses refer to the numbers in the previous week. Although the epidemic of measles in London continues to show a large increase in cases was reported from the LCC elementary schools—1,825 compared with 996 in the week ended April 16. The average daily admissions to the LCC fever hospitals were 60 the same as in the previous week while the number of cases under treatment in these hospitals on April 29 was 1,975 compared with 2,125 on April 22 and 2,220 on April 15. On the same day there were under treatment in the LCC fever hospitals 1112 (1140) cases of diphtheria, 775 (802) of scarlet fever and 287 (279) of whooping cough. The figures in parentheses refer to the numbers recorded in the previous week. Notifications in the eleven metropolitan boroughs in which measles is notified were for the week ended April 30 581 (719) distributed as follows: Battersea 69 (87) Bermondsey 57 (58) Finsbury 24 (23) Fulham 25 (25) Greenwich 121 (103) Hampstead 20 (22) Lambeth 56 (128) St Pancras 55 (74) Shoreditch 29 (32) Southwark 20 (63) Stepney 39 (44). In Scotland 676 cases of measles were recorded compared with 798 and 724 respectively in the two preceding weeks the figures for Glasgow were 304 (175) Dundee 126 (295) Aberdeen 94 (190) Edinburgh 67 (74) Falkirk 11 (39). The figures in parentheses refer to the numbers in the previous week. During the week under review there were 27 deaths from measles in the 16 principal towns in Scotland compared with 24 and 33 respectively in the two previous weeks. Of the 27 deaths 11 occurred in Glasgow 6 in Dundee 4 in Aberdeen 2 in Paisley and 1 each in Edinburgh, Motherwell, Coatbridge and Kilmarnock. In Northern Ireland there were 22 cases of measles—18 in Belfast and 4 in Portrush—and 1 death in Portadown. During the week there was 1 death from measles in Eire (in Dublin).

## Typhus

The epidemic of typhus in Algeria appears to be abating there being 35 cases in the week ended April 16 compared with 56 reported for the previous week and 82 in the week ended April 2. Of the 35 cases there were 6 at Oran and 4 at Algiers. In the week ended April 23 198 cases of typhus were reported in Morocco and 16 deaths compared with 243 cases and 19 deaths in the previous week. Of the 198 cases there were 64 at Meknes 34 at Chaouia and 20 at Rabat. During the same week in Egypt there were 149 cases with 22 deaths compared with 150 cases and 11 deaths in the previous week. The largest number occurred at Qena where 40 cases were reported. Beheira 22 cases Giza 16 cases and Minutiva 15 cases. During the same week there were 25 cases of typhus in Tunisia compared with 32 in the previous week 16 in Bizerta 2 each at Suk-el Arba, Tunis and Susa and 1 each at Le Ker Gabes and Military Hospital.

## Yellow Fever in Nigeria

The diagnosis in a suspected fatal case of yellow fever (notified on April 23) at Keta in a European has since been confirmed.

During 1937 notifications were received of 19 cases of yellow fever in Nigeria. The following table gives an analysis of the cases.

	Total Cases	Dead	Recovered	Probable	Not proved
African	5	4	1	5	—
European	10	6	4	—	2
American (white)	4	2	2	4	—
Total	19	12	7	13	2

\* Prov. d. p. thology - or by post-mortem exam.

## Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR BRITISH MEDICAL JOURNAL BMA HOUSE TAVISTOCK SQUARE WC1

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, BMA House Tavistock Square WC1 on receipt of proofs. Authors overseas should indicate on MSS if reprints are required as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager. Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, BMA House, Tavistock Square WC1.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

### QUERIES AND ANSWERS

#### Alopecia

R J C writes. A male patient aged 40 in excellent general health and without any relevant disease of the scalp is suffering from falling of the hair (defluvium capillorum). A year ago he had a luxuriant growth of hair. Is any treatment known that will prevent the remaining hair from falling and promote renewed growth of the hair that has already fallen?

#### An Internal Sanitary Pad

Q Y writes. In these days of general interest in the National Physical Fitness Campaign I feel that many of us would welcome an expert gynaecological criticism of the much-advertised internal sanitary tampon. As a woman general practitioner I am frequently asked about this method of sanitary protection and, as in the case of your other correspondents hesitate to recommend it. It seems to me that the advantages are more than outweighed by the disadvantages. Apart from the obvious objection, both psychological and mechanical to its use in the virgin, and its insufficiency in cases other than those of oligomenorrhoea, surely it is reasonable to suppose that the resultant obstruction to free drainage may lead to infection. Less likely but nevertheless worthy of note is the possibility of rectal stricture and partial urethral obstruction from pressure. I would be grateful for other opinions on this method which appears to me contrary to all we have been taught about the hygiene of menstruation.

#### Painful Uraturia

Dr I P MYERS (Brighton) writes. A patient of mine, a male aged 36 and unmarried was suddenly seized with violent pain in the left loin which was referred to the abdomen and down the left ureter and associated with vomiting. His temperature was 99 F. In the next six hours the pain increased in intensity but the urine was clear and there was no haematuria. His abdomen became very distended and the vomiting persisted. He was removed to a nursing home where investigation revealed no abnormality in the bladder, ureter or kidneys. As the patient still had severe pain and distension exploratory laparotomy was undertaken. At operation in acute condition of the pancreas was found with evidence of old standing pancreatic fibrosis. The pancreatic tract was drained through the gall bladder and after three weeks he made an apparently good recovery. The patient was a stout man and very active. He did not lose much weight and went on very well for one year. The urine was normal containing no sugar, albumin, or casts. He has since had two similar attacks, which are so

severe as to require the administration of morphine. Each attack is associated with the passing of large quantities of urates. An attack ends dramatically, one specimen of urine being loaded with urates while the next is clear and normal in every way. Dietetic treatment and total abstinence from alcohol do not seem to modify the condition in any way. I have tried diuretin (Knoll) two tablets every four hours during the attack, and I imagined that an attack was aborted by this means, but similar treatment in the last two attacks has failed to give relief. I would welcome any advice or suggestion.

#### Income Tax

##### *Income from Abroad*

'G S' says that his wife has some Indian shares and Indian income tax is deducted from the dividends. He is assessed to United Kingdom income tax also. Is this correct?

\*\* Yes—income tax is payable in both countries but "Dominion Income Tax Relief" is allowable from the tax assessed in this country. 'G S' should inform the inspector of taxes that he claims that relief and should forward the dividend counterfoils as certificates of payment of the Indian tax.

### LETTERS, NOTES, ETC.

#### Vitamin Therapy and Uterine Function

Dr ERIC KENDERDINE (Coventry) writes. It may be of interest to record the contrast between two very dissimilar labours of the same patient. The first terminated at seven months in a labour lasting twenty-two hours. The baby weighed 5 lb and did not survive, the pains were severe throughout. In the second pregnancy vitamin E was administered to avoid another early termination, and at the eighth month calcium and vitamins A and D were also given. The second labour was heralded by a loss of clear mucus at 3 p.m. and pink-stained mucus at 6 p.m. there being no information as to when the membranes ruptured. The first recognizable pains came on at 7.40 p.m., when the patient went to bed. An 8 lb baby was born naturally under an anaesthetic at 9.20 p.m. This case would seem to show the beneficial effects of the vitamins concerned in improving uterine function, both placentas and both presentations were normal.

#### Treatment of Bacillary Dysentery

Dr F G CAWSTON (Durban, S. Africa) writes. For speedy relief and an early return to normal it would be difficult to find a better treatment for bacillary dysentery than sodium sulphate in 15 grain doses two hourly, just flavoured with peppermint. I was glad to have the opportunity of treating a colleague's wife in this way recently thus averting the frequent purges to which Dr Frank McCay refers (*Journal* February 26, p. 488). This method proved useful in dealing with cases among the troops at the Rhodesia Heights cantonments in 1917.

#### Injectors—A Protest

"X Y Z" (London, W) writes. It is time that we protested against the prevailing fashion of injecting which could just as well be given by the mouth. I know one man who seldom gives a drug by the mouth but he uses a needle. Even for an ordinary cold or influenza he goes the needle. A patient of my own fell into the hands of one of these injectors. There was no improvement in her condition but several injections made her a sadder but a wiser patient. In one case death from septicaemia followed a hypodermic injection into the thigh. Again, why should sulphamides act so well when given by mouth be so often given hypodermically, intramuscularly, or intravenously?

We have received from Messrs F J Smith and Sons Limited, the eighth edition of *Elastoplast* and also the fourth edition of *Cellon*. These small volumes are well illustrated and contain on application to Smith and Nephew, Limited, Hull.

# EPITOME OF CURRENT MEDICAL LITERATURE

## Medicine

### 391 Gold Therapy and Blood Sedimentation

J. M. M. STEVEN (*Tubercle* February 1938 p. 211) in the controversy regarding the influence of gold therapy on the blood sedimentation rate agrees with those authors who declare that it has no immediate direct specific effect. After forty-three injections of sodium aurothioglucose a rise was noted after thirty-two a fall and after three no change in the sedimentation rate. In 10 per cent of cases a sudden drop was noted but the author was unable to accept this as a favourable sign—he regarded it as being due rather to some error in technique. Steven found that the rise or fall of the sedimentation rate in the course of gold therapy was small—namely 3 mm. Gold is stated to have a two-fold action: (1) a tuberculin-like action increased capillary permeability around the tuberculous focus permitting the absorption of toxins; (2) a metallic action similar to that produced by any heavy metal. The author believes either that this theory is erroneous or that the amount of tuberculin absorbed from the focus after each injection is so small as to be without influence on the sedimentation rate. He thinks that it should the latter view prove to be correct gold will cease to be used therapeutically in tuberculosis. Steven is of the opinion that the blood sedimentation rate might well be used as a reliable criterion in the study of the therapeutic value of gold in pulmonary tuberculosis.

### 392 Gastritis and Silicosis

B. NARDONE (*Polichinico Sez. Prat.* March 14 1938 p. 469) who records two illustrative cases in men aged 38 and 40 respectively states that in the course of pneumoconiosis it is not unusual to find some degree of gastroenteritis which is due to the toxic action of the small quantities of dust swallowed. This condition is a recent discovery and has been confirmed by gastroscopy and x-ray examination. It is important in that the occurrence of a syndrome consisting of anorexia vomiting abdominal pain and intestinal disturbances together with a certain degree of asthenia loss of weight and tracheobronchitis in the course of pneumoconiosis may suggest a diagnosis of tuberculosis and lead to the patient being sent to a sanatorium where he may readily become infected. Prophylaxis consists in good ventilation of the workrooms the wearing of protective masks and washing out the mouth before meals. As regards treatment the best results are obtained by gastric lavage three or four hours after the last evening meal small meals at frequent intervals and the administration of bismuth dilute hydrochloric acid and sedative expectorants.

### 393 Endocarditis Lenta

L. BELTRAMETTI (*Omnia Med.* November-December 1937 p. 567) reviews at length the present knowledge of the aetiology symptomatology diagnosis and treatment of endocarditis lenta due to *Str. viridans*. He describes two cases in which the symptoms were atypical but the diagnosis was established by the isolation of the organism from the blood and urine. The first patient was treated by intravenous injections of rivanol by blood transfusions and by an autogenous vaccine but died. The second gave a history of rheumatism and on examination was found to have signs of mitral and aortic insufficiency and a daily afternoon pyrexia. *Str. viridans* was found in the blood. She was first treated by an autogenous vaccine which produced no improvement and was then given several blood transfusions after which the general condition improved and the fever disappeared. She returned home but after eight months was readmitted to hospital with a recrudescence of symptoms. The organism was

still present in the blood and urine. She was given arsenic benzol intravenously in doses of 0.2 gramme over a period of seven months the total amount injected being 3.5 grammes. Simultaneously during a period of five months she had twenty-one blood transfusions each of 200 c.c.m. After the third month of treatment the blood culture became negative for *Str. viridans* and the pyrexia disappeared. The patient put on weight and felt well. Unfortunately towards the end of the sixth month in hospital her temperature rose again and she had a haemoptysis. Tubercle bacilli were found in the sputum and radiological examination revealed the presence of an active pulmonary tuberculosis. She is at present in a sanatorium and is improving.

## Surgery

### 394 Carcinoma of the Colon

D. ADAMS (*New Engl. J. Med.* January 27 1938 p. 160) has studied seventy cases of carcinoma of the colon treated over a period of eleven years. There were two cases in the second decade of life and a maximum of thirty cases in the sixth decade. Cases have been recorded in the newborn and in infants and the possibility of this condition being present should not be overlooked at any age. In the series reviewed there were forty-five females to twenty-five males but this ratio has been reversed in other series of cases. It is considered that 15 per cent of all cancers affect the large bowel the figures for carcinoma of the colon and for carcinoma of the rectum being equal. The areas of the colon affected in order of frequency are the sigmoid the transverse colon and the splenic flexure. There is a higher proportion of cases with left-sided involvement in this and in other series reported. The aetiology of the disease is unknown although chronic irritation from hard faeces or from colitis or amoebic dysentery have been suggested as contributory factors. Pain which was the most common symptom in Adams's patients varied from a dull gnawing sensation usually near the region affected to the generalized paroxysmal type of pain caused by obstruction. In 85 per cent of cases there was constipation while nausea vomiting bleeding from the bowel weakness and diarrhoea were other symptoms complained of. Of the seventy cases reviewed sixty received operative treatment of various kinds. The largest group of twenty-seven was treated by resection of the affected part of the colon with bowel decompression in some cases. The mortality in this group was 50 per cent. Adenocarcinoma was reported in all cases and metastases were found to extend locally to regional lymph nodes and to distant parts. The importance of early diagnosis and treatment is stressed. The average duration of life for the thirteen patients who died after discharge from hospital after bowel resection was two years, there are seven patients in the whole series who are still alive and well.

### 395 Renal Function after Trauma

H. DOMRICH (*Z. Urol.* 1938 32 2 78) points out that measurement of the urine secreted after injury to a kidney gives little precise information concerning the extent or severity of the trauma for true oliguria is indistinguishable from perirenal infiltration—a definite delay in methylene-blue excretion is not constant. The general clinical signs are often disproportionate to the damage done. Retrograde pyelography has given useful information and shown that considerable infiltration into the renal parenchyma or perirenal tissues is not inconsistent with excellent results from conservative treatment such treatment may however, be technically difficult and certainly increases the

danger of secondary infection. Excretion urography has been tried in a few cases, but whether cessation of renal function soon after injury justifies operation has not yet been decided. Domrich has followed, by skiagrams taken after the intravenous injection of perabrodil, the changes in excretion after experimental injury to the kidney in rabbits. He finds that if the crushing has not been too severe urinary secretion continues, but during the ensuing two weeks the secretion from both the injured and the normal organ becomes less. It is concluded that intravenous pyelography may be useful directly after the trauma as determining the side and to some extent the severity of the injury, and that (in view of the poor remote results of conservative treatment) absence of a renal contrast shadow directly after injury justifies operative inspection and treatment of the kidney.

396

## Subdeltoid Bursitis

R. L. PATTERSON and W. DARRACH (*J. Bone Jt. Surg.* October, 1937, p. 993) have treated sixty-three cases of acute subdeltoid bursitis by irrigation. The diagnosis should be made chiefly from clinical findings. There is severe acute shoulder pain, often with localized tenderness over the bursa and limitation of external rotation and abduction, flexion and extension are free. Too much reliance must not be placed on the x-ray appearances, as the typical calcium shadows may occasionally be absent in an otherwise characteristic case. The technique of irrigation is simple. Under local anaesthesia two needles are introduced into the bursa. One enters the skin 1 inch lateral to the coracoid process, the other is introduced posterior to the greater tuberosity of the humerus. Saline is used as the irrigating fluid, and from 30 to 60 ccm are sufficient. The fluid is injected through one needle and flows out through the other. Subsequently the arm is put in a sling for a few days. Often no after-treatment—usually in the form of physiotherapy—is required. The average disability period after this procedure was well under one week in the authors' cases, and this compares very favourably with the two to six weeks' disability after operative procedures. This treatment is particularly suitable for the very acute type of case, in which pain and tenderness are well localized. It may be tried in subacute cases when physical methods have failed to give relief. Should a radiograph reveal hard dense, calcified masses lying in the bursa, however, open operation is indicated. It is important that films should be taken with the shoulder in internal and external rotation, as the deposit may be visible in only one of these positions. Similar treatment has been tried for bursitis in other regions of the body with equally good results. Recurrences have not been seen and in no case was the condition made worse by irrigation.

## Therapeutics

397

## Intestinal Infections

A. CASTELLANOS (*Bull. Soc. Pediat. Cub.* January, 1938, p. 23) who records six illustrative cases in infants aged from 15 days to 9 months states that the method of bleeding followed by blood transfusion recommended by Robertson Brown and Boyd is theoretically the best for the treatment of severe intestinal infection in infants. Its technique however is complicated and requires absolute immobility on the part of the child and a highly trained staff. The child's blood must be withdrawn through the longitudinal sinus from this site relatively large quantities of blood can be withdrawn without much difficulty and in infants it is not easy to find any vein of which the same might be said. Any superficial vein will serve for the injection of the donor's blood. The amount of blood to be withdrawn varies from 60 to 100 ccm according to the age and weight of the infant,

and then a larger quantity of blood should be injected. In Castellanos's cases this method was employed in association with the subcutaneous injection of normal saline. Five of the six infants died, and Castellanos comes to the conclusion that in severe intestinal infections in infants bleeding followed by transfusion possesses no advantages over transfusion without bleeding.

398

## Sulphanilamide in Cerebrospinal Fever

L. J. WILLIEN (*J. Amer. med. Ass.* February 26, 1938, p. 630) records five cases of meningococcal meningitis in patients aged from 18 months to 26 years, treated with sulphanilamide as follows: (1) An initial subcutaneous injection of a large dose of a saturated solution was given in amounts of about 0.05 gramme per kilogramme of body weight. (2) The drug was also given by mouth every four hours day and night. (3) The dosage was graduated from an upper limit of 15 grammes every four hours according to the size and age of the patient and the severity of the attack. (4) Reduced doses were continued for about ten days after the normal condition had been reached. (5) Sodium bicarbonate was given grain for grain with the sulphanilamide to combat acidosis. The results were satisfactory even when the drug was given by mouth only.

## Diseases of Children

399

## Vitamin C in Childhood

FRANCIS M. MESSERLI and FRANZ HEIMANN (*Rev. Allerg.* January, 1938, p. 20) have carried out 4911 analyses of the urinary content of vitamin C in a series of Lausanne children. They consider that repeated estimation of the vitamin C content of the urine is a satisfactory means of determining the presence of hypovitaminosis and forms a useful adjunct to other methods of gauging nutrition. Almost 90 per cent of the children eliminated very small amounts of vitamin C throughout the year, showing a deficiency present in all classes of the community.

400 G. MEYER HORSTE (*Med. Klinik* January 25, 1938, p. 105) discusses the importance of vitamin C in childhood. He advocates the supply of adequate quantities of this vitamin to growing children. The results of lack of vitamin C are first manifest in the teeth at a time when the other organs still show no pathological changes. The teeth show a degeneration of the odontoblasts which leads to the formation of new connective tissue in the teeth. These changes may regress under the influence of large doses of vitamin C but the ordinary people's diet is poor in this vitamin. This accounts for the high proportion of bad teeth found among military recruits.

401

## Mortality in First Ten Days of Life

COURTOIS and LECOQ (*Gynecol.* December 1937, p. 704) have studied the causes of death in 3460 newborn infants in the first ten days of life. They found there was a mortality of 8.5 per cent. The causes were subdivided into (1) those directly due to foetal primary mortality—and (2) those due to other circumstances—secondary mortality. The causes of the primary mortality, they state, are asphyxia, meningitis, and cranial fractures. Actiological factors of secondary mortality include severe uterine contractions, separation of the placenta, pressure on the foetus, maternal asphyxia. Treatment should be directed towards clearance of the respiratory passages, and intravenous injections of adrenaline should be given in some cases. Meningeal haemorrhage is responsible for 0.6 per cent of foetal deaths at term and of 6.4 per cent of deaths in the first ten days of life. Term lumbar or ventricular puncture establishes the diagnosis in all cases. Treatment consists of the following:

tion of coagulants injection of hypertonic saline by lumbar puncture intravenous injection of glucose and incision of the inferior fontanelle and duramater. Cranial fractures may require reduction. Haematomata should be sought for. The causes of the secondary morbidities include prematurity meningeal haemorrhage congenital malformations, and infection. Prophylactic treatment of the premature infants to avoid nec of birth trauma infections of all kinds changes in temperature and alimentary disturbances. The main congenital malformations producing neonatal death include those of the heart mus rectum alimentary canal and urothra. The authors state that the majority of cardiac malformations are due to syphilis. Of neonatal infections syphilis is the most important for it is the cause of 45 per cent of all deaths in the newborn. The authors strongly recommend low Clostridium section in all cases in which regular and strong punishment to advance labour from four to twelve hours after rupture of the membranes. The operation is said to reduce by 75 per cent deaths due to asphyxia by 55 per cent those due to trauma and by 40 per cent those due to debility and syphilis.

## 402

## Cardiac Changes in Nephritis

M. I. RUBIN and M. RAPAPORT (*Am J Dis Child* February 1938 p 244) examined fifty-five children with acute haemorrhagic nephritis and found varying degrees of cardiac involvement in fourteen. They noted dyspnoea cardiac enlargement muffled heart sounds tachycardia systolic murmurs gallop rhythm enlargement and tenderness of the liver pulmonary and peripheral oedema and electrocardiographic changes. The writers emphasize the importance of hypertension which was found in all the fourteen cases as a cause of cardiac decompensation. The intramuscular injection of magnesium sulphate was found to be valuable both as a prophylactic and as a therapeutic agent. The giving of unlimited fluids which has been recommended with the idea of diluting toxins and producing diuresis is deprecated is likely to produce a further rise in blood pressure and precipitate a cardiac catastrophe.

## 403

## Brucella melitensis Meningitis

R. A. BLACK (*Arch Pediat* December 1937 p 702) records the case of an infant who died from this rare infection. The infant had all the symptoms of a severe meningitis and the agglutination test was positive with *Brucella abortus*. Similar agglutinations were found in the mother and father. Lumbar puncture showed that the cerebrospinal fluid pressure was slightly increased the fluid was clear there were 3 cells per cmm and no organisms were seen. Repeated examinations of the urine were negative throughout the illness. At necropsy it was found that there was an increase in the pressure of the cerebrospinal fluid and the subarachnoid space was filled with a yellow white fibrous exudate. On microscopic examination this exudate contained strands of fibrin and numerous cells. All the vessels were injected and the cortex of the brain was soft and oedematous. Two methods of transmission of brucella infection to man are recognized (1) by the ingestion of infected dairy products such as raw milk cream and butter (2) by the handling of infected uncooked meats. Children however appear to possess a relative immunity.

## 404

## Infantile Erythroblastic Anaemia

J. CAMINOLETROS (*Ann de Med* January 1938 p 27) describes his work on infantile erythroblastic anaemia among the inhabitants of the Eastern Mediterranean littoral. The disease begins in the first few months of life and is characterized by enlargement of the liver and spleen marked pallor and recurrent attacks of intermittent pyrexia. Until the second year of life diagnosis depends on (1) the presence of large numbers of erythro-

blasts in the blood and (2) increased resistance of the red blood cells to hypotonic saline. Later changes in the skull are seen and a Mongol like facies develops. The author discusses the cases described by Cooley and the difficulty of differentiating this disease from acholuric jaundice and von Jaksch's anaemia. Forty-two cases of infantile erythroblastic anaemia were examined between 1927 and 1934 and thirty-four cases since then. A large number showed the Mongol like facies and retarded growth with genital hypoplasia was noted in the older infants. Enlargement of the liver and spleen was an early and constant feature. Unlike acholuric jaundice there was no enlargement of the spleen during the pre-reveal periods but the number of erythroblasts and the bilirubin content of the serum showed marked fluctuations. There was a marked polymorphonuclear leucocytosis a characteristic feature being the presence of young cells with bilobed nuclei. In both the splenic pulp and the marrow of the sternum large numbers of immature red cells and immature leucocytes of the myeloid type were found. Lowered fragility of the red cells was constantly present. Radiological examination of the skull pelvis shoulders hands and feet showed osteoporosis. In the long bones the outstanding feature was enlargement of the medullary cavity. The author distinguishes two new forms of erythroblastic anaemia (1) the anaemia of earth eaters which occurs in older infants and is associated with slight bone changes and (2) erythroblastic anaemia with crescent-shaped red cells. Eleven cases fell into the former group and one into the latter. In this case the change in the red cells was incomplete. Of the whole group the great majority were dead two years after the initial examination.

## 405

## Niemann Pick's Disease

F. R. B. ATKINSON (*Arch Dis Childh* October-December 1937 p 241) gives a short summary of the recorded cases. Niemann Pick's disease is congenital and familial and affects chiefly the Jewish race. It is confined to children. There is enlargement of the liver and spleen with a brownish pigmentation of the skin and often a Mongolian appearance. In some cases it has been associated with Tay Sachs's disease. The symptoms usually begin quite early in life with vomiting and gradual weakness death nearly always takes place within two years. Other characteristics are anaemia an increase of the lipoids in the blood and attacks of fever. Mental retardation is common. The liver and spleen are always enlarged and have deposits of round or polygonal cells with increased lipoids. The brain is markedly changed and the optic disks often show cherry red spots similar to those found in Tay Sachs's disease. The cholesterol phosphatides and neutral fats are all much increased in the blood. No treatment is of value except that x-rays may cause a temporary improvement.

## 406

## Anterior Poliomyelitis and Varicella

HERBERT STUX (*Le Nourrisson* January 1938 p 31) describes an interesting case arising during the early stage of an epidemic of anterior poliomyelitis of a girl aged 1 year and 5 months who had been in contact with a case of measles and was given 40 ccm of adult serum. Five days later she developed a febrile illness on the eleventh day of which there suddenly appeared a flaccid paralysis of the right arm. The pyrexia continued for three weeks but there was no eruption. After three months the paresis had almost completely recovered. Four months after the original illness she had a mild attack of varicella which was complicated on the fourth day by a sudden flaccid paralysis of the right hand. Four months later only a slight atrophy of the muscles of the hand remained. The author discusses the relation between anterior poliomyelitis and varicella. He considers the paresis to be a true anterior poliomyelitis rather than a varicellar poliomyelitis. The long prodromal period

and the persistent pyrexia are unusual features in the case described. A neurotropic virus latent in the body, through the agency of an intercurrent infection, either by increased virulence of the virus or by lowered immunity in the host may give rise to the disease. Herpes in pneumonia, encephalitis following the exanthemata, and the relation of chicken-pox to herpes zoster are also examples. Such biotropism occurs especially when the virus has a neurotropic character. A satisfactory explanation of these facts has not yet been given.

437

## Erysipelas in Infancy

U AVELLONE (*Pediatrics* Naples, February 1, 1938, p 114) discusses 102 cases of erysipelas in infants and children with particular regard to the age, sex, and seasonal incidence and the mortality. The mortality rates at different ages were: under 1 month, 25 per cent; 1 to 6 months, 14.8 per cent; 6 to 12 months, 7.1 per cent; over 12 months, 5.1 per cent. Avellone suggests that these relatively favourable results may be due not so much to the treatment given (vaccines, haemotherapy, prontosil, ichthyol paste, etc.) as to various climatic and other factors.

## Obstetrics and Gynaecology

408

## Antutrin S Test

A SHARMAN (*J Obstet Gynaec Brit Emp* February, 1938, p 82) has investigated the antutrin S test for the diagnosis of pregnancy in 400 cases, using the technique of Gilfillan and Gregg (*Amer J Obstet Gynec*, 1936, 32, 498). Of his cases 196 were pregnant and 204 non-pregnant women. A positive pregnancy reaction was obtained in 204 cases, of which 177 were proved pregnant and twenty-seven non-pregnant, the error being 13.2 per cent. A negative pregnancy reaction was obtained in 122 cases of which 116 were not pregnant and six were pregnant, the error in this group being 4.9 per cent. In seventy-four cases the reaction was doubtful, thirteen of these patients were pregnant and sixty-one were not. Sharmman concludes that the test in its present form is not dependable and is not so accurate as the Aschheim-Zondek reaction. This is unfortunate, as the test is simple and inexpensive. It has interesting possibilities and should be further studied. Employing the same technique, but using adrenaline in thirty-four cases and pituitrin (posterior substance) in fifteen cases the author failed to obtain uniform results in either pregnant or non-pregnant women.

409

## Pneumothorax in Pregnancy

A LONGO (*Riv Patol Clin Tuberc* February 28 1938, p 100) describes six cases of pregnant women suffering from pulmonary tuberculosis which was treated by the induction of an artificial pneumothorax. Their ages varied from 19 to 35 and the duration of their illness before admission to the sanatorium from a few days to four years. In some of the cases the onset was insidious in others very rapid. One patient gave birth to twins spontaneously at the eighth month in all other cases a normal delivery occurred at term. Low forceps were applied in one instance for uterine inertia. In all six cases the puerperium was uneventful. Five patients were greatly benefited by the collapse therapy. The one unfavourable case was that of a woman of 35 who after progressing remarkably well as a result of a bilateral initial pneumothorax decided to return home at the seventh month and did not attend for refills. She had rapidly worse after delivery and her pulmonary condition grew later. This seems to illustrate the author's view that the chief danger in pregnancy associated with pulmonary

tuberculosis lies in the hyperventilation of the lungs which occurs after delivery, when the diaphragm is free to resume its full excursion, thus giving rise to "homogeneous aspiration of tuberculous material." He therefore advocates a fairly large refill as soon as possible after delivery in order to compensate for the increased diaphragmatic movements. Conversely, he appears to agree with those authors who consider that pregnancy may exercise a favourable effect on pulmonary tuberculosis by limiting the excursion of the diaphragm. Longo concludes by urging that pregnant women suffering from pulmonary tuberculosis should be admitted to suitable institutions as early as possible, so that collapse therapy may be instituted at the most favourable moment as he sees in this method of treatment a means of avoiding the necessity for interrupting the pregnancy.

## Pathology

## Vaccination against Typhus Fever

P RADLO (*Arch Inst Pasteur Tunis*, 1937, 26, 667) reports on the vaccination of 13,980 persons against typhus fever in Poland during the years 1933 to 1936. Weigl's method was used, consisting in the injection of infected louse intestine ground up and suspended in 0.5 per cent phenolized saline. Originally Weigl used the intestines of 250 lice for the vaccination of a single subject. Owing to the expense involved this was subsequently reduced to 100 and then to 90. The present author has worked with even smaller numbers. Thus in thirty-five localities a quarter of the 13,980 vaccinated persons received only one to ten lice intestines per person, half received ten to twenty, and the remaining quarter twenty to thirty. Judging from the results obtained the degree of active immunity produced by the smaller doses did not differ noticeably from that produced by the larger ones. Altogether sixty cases of typhus were observed among the vaccinated subjects during the four years. In fifty-five of these the illness began during or immediately after vaccination. Only five persons contracted typhus fever more than five months after vaccination. One of these had received one louse intestine, two had received four or five intestines, and two had received ninety intestines. In all the vaccinated subjects the fever pursued a benign course.

411

## Cold and Influenza Vaccines

E C ROSENOW and F R HEILMAN (*Amer J Clin Pathol* January, 1938, p 17) report studies on the protection against colds and influenza given by vaccines prepared from streptococci that had been preserved for not more than a year in dense suspensions in a mixture of water and 25 per cent sodium chloride solution. Vaccines were prepared as needed by dilution of the dense suspension with sodium chloride solution followed by heating at 56°C for use by injection or with a syrup when it was required for oral administration. Used prophylactically on 7,000 persons, the vaccines effected a reduction in incidence of colds and influenza in 91 per cent of cases. The incidence of colds or influenza in vaccinated persons was reduced to one third or one half of that in non-vaccinated persons living under comparable conditions. In treating over 5,000 patients with colds, influenza, pneumonia, chronic bronchitis or chronic sinusitis benefit from the vaccines was found in about 90 per cent of all cases in each disease. The findings in human subjects were supported by the results of experiments on mice and subcutaneous vaccination of mice. In other experiments rats and mice immunized orally by vaccines prepared from old strains of streptococci and pneumococci were protected against recently isolated strains of these cocci and pneumococci.

# In the treatment of MACROCYTIC ANAEMIAS

This palatable liquid extract of hog's stomach contains Hemopoietin in stable solution. The stomachs are treated immediately after killing to extract the Ant anæmic Factor in active condition producing a bland liquid of pleasant flavour to which the name HOGASTRIN has been given.

A dose of two teaspoonfuls in a little water three times a day for a fortnight then reduced to one teaspoonful will invariably give good results in the treatment of all Macrocytic Anæmias.

### Vitamin Concentrate or Natural Food?

The normal daily dosage of Bemax, 1 c., 1-ounce, provides 200 International units of Vitamin B<sub>1</sub>, which is from four to ten times as much as the recommended daily dosage of certain Vitamin B<sub>1</sub> concentrates advertised to the medical profession. If a higher intake is required, it is possible to supply as much as 600 to 800 units of Vitamin B<sub>1</sub> daily by the administration of three to four tablespoonfuls of Bemax, and this in an entirely natural form at only a fraction of the cost of concentrates.

The Vitamin B<sub>1</sub> potency of Bemax is assured by biological assay of every day's output and is from 12-15 International Units per gramme, about 400 units per ounce.

## BEMAX

A unique natural source of accessory nutritional factors

Vitamin B<sub>1</sub>—400 I. U. per ounce

Vitamin B<sub>2</sub>—15 I. U. per ounce

# THROMBIN-COAGULANT-MAW DRESSINGS

## FOR THE MAJOR OPERATION OR THE MINOR CUT

Some time ago we announced the production of Thrombin Coagulant Maw, a preparation of remarkable efficiency for clotting blood

We now offer a range of Surgical Dressings known as Thrombin Coagulant Maw Dressings to which this preparation has been applied with such regard for the scientific principles concerned both chemical and physiological that we venture to suggest a new method of treatment has been found

H. PHYSIOLOGICALLY CORRECT FIRST DRESSING

Whenever a wound is accessible to the application of a Dressing TCM Dressings will be found of great value in all cases requiring hæmorrhage control. They are very reasonable in price and represent a true economy of your own time and money whenever hæmorrhage has to be treated

**A PRODUCT OF THE MAW LABORATORIES**

*Full particulars on application to*

## DON'T JUDGE THE ABILITY OF THIS ELECTROCARDIOGRAPH BY ITS SIZE

Because the Victor Electrocardiograph seems to you so extremely small in size and its low price places it easily within your means don't make the mistake of overlooking its ability to produce exact graphic heart records of real diagnostic value

Its correct design and self contained power supply accounts for this high sensitivity and unusual compactness. And because it is a precision instrument you can rely upon its

tracings to point the way to better earlier diagnosis and to more exact prognosis

If you have not yet taken the opportunity to see a practical working demonstration in your own consulting room you cannot fully appreciate its possible advantages in your practice

For a demonstration or a booklet of unusually interesting information on electrocardiography simply fill out and post this coupon you will not be obligated

A Private Home for the treatment of a limited number of Ladies and Gentlemen suffering from Nervous and Mental Illness. Temporary Patients receive treatment. For Ladies and Gentlemen at the recommendation of the Local Medical Officer. Apply to Dr J A S. Tel. 4411. Telegraphy Small Heath 513.

# Budapest Spa

The distinguished record of successful cures effected in Hungary's delightful capital indicates in some slight measure the remarkable healing powers of its natural water springs

All told there are more than 80 sulphur and radio active thermal springs (96° F to 162° F) in addition to over 200 mineral water springs. These, it is calculated, produce 11 million gallons of curative waters daily

Unsurpassed in comfort and efficiency, the modern Spa establishments remedy many kinds of disorders particularly of Rheumatic Diseases, Sciatica, Arthritis, Fibrositis, Diseases of Women, Chronic Skin Disorders, etc

As additional incentives to the visitor, Budapest offers all the amenities and attractions of a large metropolis and the glorious surroundings that have made Hungary famous the world over

Three weeks treatment in Budapest including accommodation at Spa Hotel sight seeing tips taxes and second class ticket from London costs only £32 15 0

# ROYAL NAVAL MEDICAL SERVICE.

Vacancies exist for Medical Officers in the Royal Navy and applications are invited for entry in July 1938

Candidates below the age of 28 years are preferred and they must be registered under the Medical Acts. No examination in professional subjects will be held but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years, which if desired is usually extended to five years at the discretion of the Admiralty.

At the end of three years' service officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000.

At the end of five years Short Service permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Full opportunities exist for transfer to the permanent list, and periods of unemployment or half pay are very rare. The assistance of private income is not necessary for the purpose of supplementing official pay and allowances.

Opportunities are available for officers on the permanent list for post graduate study, to specialise, to take higher examinations and to obtain further qualifications.

Naval Medical Officers are included in the Scheme for Marriage Allowance under the same conditions as for other Naval Officers.

Copies of the regulations for entry and conditions of Service, including rates of pay, allowances and retired pay may be obtained from the Medical Director General of the Navy, Admiralty, SW 1, and from the Deans of all Medical Schools.

Applications for entry from intending candidate, must be received not later than 31st May, 1938

## MEDICAL STAFF - PRISON SERVICE (ENGLAND AND WALES)

Applications are invited for the post of Medical Officer CLASS II in the Prison Service. Commencing salary £3 per annum with annual increments of £1 per annum with an initial house allowance of £100 per annum. The post is permanent.

Candidates must be fully qualified and preferred will be given to those who have held the post. It is desirable that candidates should have had experience in medical duties and in medical practice and are between the ages of 24 and 35 years. The Commission is for three years from the date of appointment.

Of the three classes of Medical Officers, Class II and two are Class I. From Class II to Class I a salary of £100 per annum is payable. From Class I to Class II a salary of £100 per annum is payable. From Class I to Class II a salary of £100 per annum is payable. From Class I to Class II a salary of £100 per annum is payable.

Forms of application can be obtained from the Secretary (Prison) Prison Commission, 11, Old Bailey, London E.C.4.

# A FEW SPECIALITIES OF F. DAVIDSON & CO.

Makers of Optical and Electro-Medical Appliances (Estd 1890)

143-149, GREAT PORTLAND STREET, LONDON, W.1

## THE "DAVON" IMPROVED RECTOSCOPE

Suggested by Philip H. Daisley Esq. M.F. Ch.B. Ed. who writes in the B.M.J.

Having been dissatisfied for some time by all the various types of proctoscope on the market I have devised a model for use in the injection of hemorrhoids. The advantages of this new model are that the whole operative field is visible at the same time that the hemorrhoids do not project into the lumen of the instrument and that there is no obdurator to cause discomfort to the patient and to be a nuisance to the operator. The instrument has been made for me by Messrs F. Davidson & Co. who are supplying it with illumination from a battery in the handle or from a spirit battery.

The lamp is protected by a glass window so that the speculum can be cleaned when in position.

Price with spare Bulb (either pattern) £2 15 0

"Davon" Dry Battery 0 7 6

21/9/37 The present Davon Battery bears the date 2/6/33 and is only just at the end of its useful life.

## 'DAVON' LARYNGO-PHARYNGOSCOPE

(Patent London)

THE INSTRUMENT WITH PERFECT OPTICAL SYSTEM, PERFECTLY FINISHED

I find your laryngo-pharyngoscope a useful instrument and have been able to obtain excellent view of the posterior nares, pharynx and larynx with it.

M.R.C.S. L.R.C.P.

With Protecting Mask Handle and Cords £6 0 0

'Davon' Dry Battery for above 0 7 6

With 'Davon' Battery and Rheostat in

Walnut Box 7 10 6

With Battery in handle (not the 'Davon') 6 0 0

In Walnut Box 6 10 0

Or Complete with Davon Electric Amplifier for diagnosis operating asphyxia and morbus in Oak Case 9 0 0

## THE "DAVON" A.C. MAINS PORTABLE TRANSFORMERS

EARTH FREE AND WITH OUR ABSOLUTE GUARANTEE BEHIND THEM

No. 83 FOR LIGHT (up to 12 volts) & FOR CAUTERY  
Size 11 x 8 1/2 x 6 1/2 Weight 15 lbs Price £6 10 0

A CATALOGUE DESCRIBING FULL RANGE OF "DAVON" DIAGNOSTIC AND TREATMENT SPECIALITIES WOULD GLADLY BE FORWARDED, POST FREE, ON REQUEST

## The "DAVON"

Self Illuminated

## SIM'S-FERGUSON'S STERILIZABLE VAGINAL SPECULUM

Price complete £2 10 0

Can be supplied with obdurator for the Ferguson portion at an additional cost of 12s 6d

I have found all your instrument most reliable and satisfactory. — I.R.C.P. I.R.C.S. L.N.

## "DAVON" DIRECT VISION OPHTHALMOSCOPE A GREAT AID TO DIAGNOSIS

Gives a clear, magnified image of the fundus without corneal reflex in bright light, without dilatation of the pupil and at an approximate distance of 7mm from the patient. Price complete in leather wallet and spare 4-volt bulb £5 0 0

I am delighted with your ophthalmoscope and stethoscope. — M.R.C.S. L.R.C.P.

## THE "DAVON" COMBINED ADULTS' & CHILDREN'S SIGMOIDOSCOPE

WITH CONCEALED DISTAL LIGHTING FLUORIMINANT JACK CHAIR CHROMIUM PLATED

Complete with highest grade Universal Telescope Bellows, etc £15 10 0

# A Triumph of Emulsification

THE OILY RING AROUND  
THIS DROP TELLS THE STORY

The ring around the drop tells the story. A drop of Agarol on blotting paper holds firmly together. Try this with a poor emulsion and you will soon see the mineral oil being taken up by the blotting paper, forming a greasy ring around the drop. For dependable efficacy in the treatment of constipation and allied disorders. Agarol—mineral oil, agar-agar and

phenolphthalein emulsion—has attained a reputation all its own.

Only the finest and purest ingredients are used in Agarol. Its exceptional palatability, secured without artificial flavouring, renders it acceptable to both children and adults. Agarol contains no alcohol and no alkali and, being devoid of sugar, is particularly suited to diabetic cases.

**Agarol**  
BRAND COMPOUND  
**FOR CONSTIPATION**

Supplied in bottles containing 4½, 7½ and 17 ounces

Agarol is not advertised to the public

William R Warner & Co Ltd, Power Road, Chiswick, London, W 4

## THE ESSENTIALS OF MATERIA MEDICA

Pharmacology and Therapeutics

By **R. H. MICKS, M.D., F.R.C.P.**

Professor of Pharmacology, Royal College of Surgeons in Ireland

"Is a concise account of the essentials of materia medica, and is a most useful and convenient reference for the practitioner." — *British Medical Journal* (1914)

'Have you  
seen

**'I'm Grand Master of the O.D.B.'**  
says Mr. Therm

**O.D.B.**  
Join up! Join up!  
HOT BATHS FOR ALL  
EVERY DAY!

**O.D.B. IS THE ORDER of the DAILY BATH**  
Millions of you are O.D.B.'s already! I want to card  
Everybody!

**A CLEAN SKIN IS AS IMPORTANT AS A GOOD DIGESTION**  
On normal days, an average man gets rid of just one half of perspiration  
through the countless pores of his skin. That perspiration is healthy  
conscience. But here is more than 24 hours, and it becomes unpleasant,  
dangerous. O.D.B.

**HAVE A HOT BATH EVERY DAY**  
A hot bath clears out the acid wastes of the skin, and leaves the pores free to  
do their good work. I wash the muscles, wash out (expose) the nerves,  
and at night I sleep healthy sleep. A hot bath does it. A hot bath is necessary to  
healthy living.

**YOUR BEST FRIEND IS GAS!**  
Health from hot gas — hot water from Gas! Gas  
has solved the hot water problem — for good!  
The hot Gas Heaters are cheap, economical and  
tremendously efficient. If your present hot water  
system prevents you from having all the hot water you  
want, go and ask Quaker at your Gas Showrooms.

**For FRESH HEALTH**  
Join Mr. Therm's  
**ORDER of the DAILY BATH**

my **O.D.B.**  
advertisements?

says Mr. Therm

THE BRITISH COMMERCIAL GAS ASSOCIATION is embarking on a campaign to popularise personal cleanliness, in the interests of health, fitness and, of course, Hot-Water-by-Gas. But, commercialism apart, they do feel that for the average man, woman and child, a daily hot bath cannot be other than beneficial, not only for health, but also for self-esteem. Naturally the Association is treating the subject with restraint and a sense

of responsibility. The main trend of the appeal is that daily bathing, by keeping the skin clean, obviates some of the 'natural ills that flesh is heir to' in these modern industrial days. It will be a considerable satisfaction to Mr. Therm—and on more than commercial grounds—if he can feel that the Medical Profession is with him in his plea for 'cleanliness and personal freshness'.

**O.D.B. is the ORDER of the DAILY BATH**  
the slogan used in a series of national press advertisements

When your patient says  
*"Thank you, Doctor"*

Your reputation as a physician depends on the benefit patients feel from your treatment and what they tell their friends. A grateful patient who calls to thank you personally for what you have done is going to extend your practice.

"The tonic effect of ultra-violet energy is great enough to impress the patient that something constructive and beneficial has been accomplished." A physician wrote these words after 10 years' practical experience. When you rebuild health in debilitated or toxemic cases with ultra-violet light baths, "the most vitalizing of all measures," your patients appreciate and acknowledge the benefits they have received.

It is quite simple to apply ultra-violet in any practice with the most modern equipment, the famous Alpine Sun Lamp. You can investigate easily, without cost or obligation. Post a card or use the coupon to-day.

## Belts by Roussel bring *health* as well as *beauty*

Women will always seek to improve their figure according to the fashionable line of the moment. How fortunate, then, when they can do so with a belt that is beneficial to health!

The special Roussel elastic weave that allows variations of tension over different parts of a belt enables J. Roussel to model a belt for every individual case. Surgeons and doctors can agree to their patients wearing a Belt by J. Roussel.

knowing that with the "variable tensions" feature, it can be made to exact measure and to exert pressure or support only where it is needed.

If you would like to know more about the Roussel Belt may we send you a copy of our beautiful illustrated Catalogue?

# Worth looking into..

Inside the du Maurier filter tip there are five closely rolled layers. Two of cellulose fibre have been carefully interleaved with three of pure white vegetable tissue. This allows the full flavour of Virginia tobacco to pass the lips, but keeps out the bits of tobacco and other irritants. That's why sensitive throats are so safe with "du Maurier" (either cork tipped in the red box or plain tipped in the blue box).

## du MAURIER

*the perfect cigarette with the exclusive filter tip*

TEN FOR SIXPENCE—TWENTY FOR ONE SHILLING

By evolving the

# AUDICLE

a development so new in aural science that it necessitated the coming of a new word—and the

# AUDIOSCOPE

a new and remarkable fitting technique

# SONOTONE

have placed the fitting of a hearing aid on a basis as scientific yet as simple as glasses for impaired vision—over 500 possible variations of volume amplification and pitch are available

The latest range of SONOTONE instruments, which includes air-conduction, bone-conduction and 'valve' type aids, represents the furthest point which aural science has so far reached and the final outcome of nearly a decade's intensive experimentation and research

Dealing along strictly ethical lines and welcoming at all times the goodwill and collaboration of the medical profession the SONOTONE organisation to-day operates in 55 different countries, enjoying a confidence and respect which are now world-wide

The SONOTONE consultant—the man whose business it is to analyse the patient's case and decide by actual test with the SONOTONE Audioscope which instrument and which variation of fitting exactly fit the particular case—must pass no less than five written examinations before his task is entrusted to him. Your patient is assured, therefore, not only of courteous but of expert and unbiassed treatment

SONOTONE hearing aids are not widely advertised—they are not sold on the basis of low price. We stand or fall by the comparison between the results given by our own instruments and those of lower price. If you would be interested to learn of the progress which has been made in hearing aids—of new and greater opportunities for relief which are open to your patients to-day—write for full particulars to

# "CURTIS" ABDOMINAL SUPPORT NO. 1

RTM

## for Steady, Permanent Support

The Curtis Model No 1 Support has many advantages over the old type abdominal belt. It is light in weight and is scientifically designed to give maximum support upwards and backwards to the lower abdomen with minimum constriction. The hips are given complete freedom of movement and the support itself is extremely comfortable. Leading London Hospitals and the medical profession unhesitatingly prescribe Curtis Model No 1—the most efficient support obtainable.

## A STEP FORWARD in infant feeding

Over 300 physicians report  
excellent results with remarkable  
modifier of cow's milk

**K**ARO, a natural blend of carbohydrates, has been used abroad for many years, with remarkable success, for modifying fresh cow's milk and milk powders for artificially-fed infants.

Recently, a number of physicians were asked to test Karo clinically. The results have been most gratifying. The gist of the letters received from over 300 physicians confirms the opinion of Karo given in a book on infant nutrition by a medical author: "We have found it (Karo) the most satisfactory form of carbohydrate in the feeding of normal and most sick infants."

The addition of Karo

to cow's milk or milk powder produces results fully equivalent to mother's milk.

A Karo and milk mixture has also been found of outstanding value in the case of sickly children—especially those suffering from marasmus, acidosis, cyclical vomiting, diarrhoea, constipation, and all kinds of biliousness, in digestion and nutritional disorders.

*Costs about 1½d a day*

Karo is of special benefit to mothers who cannot afford expensive diets for their bottle-fed babies. A 1 lb tin, costing 1/3, provides a ten days' supply for a three months old baby—a cost of 1½d a day. The price of the 2 lb tin is only 2/.

### ANALYSIS OF KARO

## A VALUABLE, DOUBLE-ACTION ANTISEPTIC ★

Local treatment with Sphagnol Peat Ointment gives rapid relief in the most obstinate cases of psoriasis haemorrhoids eczema and skin eruptions. The reason is that Sphagnol has a twofold action. First of all it soothes and allays irritation and burning sensations. Secondly the natural antiseptic properties of the peat distillates assist in general treatment. Sphagnol

has proved beneficial over and over again where persistent resistance has been encountered.

In case you have had no personal experience of Sphagnol, we shall be pleased to send you a clinical size sample for testing if you will write to Peat Products (Sphagnol) Ltd Dept B M J 21 Bush Lane London E.C.4

# WHOOPIING COUGH

Detoxicated Whooping Cough Vaccine (Genatosan) has proved remarkably successful. Reports received from medical practitioners state that it usually reduces the frequency of the paroxysms after the first injection, and subsequent injections almost invariably clear up the condition. Owing to the elimination of the toxic elements of the germ during the process of manufacture, this vaccine may be given to infants and young children, in doses sufficiently large to produce the desired therapeutic effect, with an absence of harmful reaction.

The following is typical of many reports received from physicians —

*"I have been making a somewhat extensive use of your Detoxicated Vaccine for Whooping Cough, and am pleased to say that the results have been almost invariably gratifying. In nearly all my cases the very distressing symptoms have disappeared after the third injection."* M.D.

Additional information regarding this Vaccine will gladly be supplied on request

## GENATOSAN LIMITED

## For Rectal and Anal Disorders

WHATEVER be the underlying cause of rectal or anal disease, logical medical treatment includes measures for rendering the motions soft and unobstructing is possible. Even after operation this holds good, since the area must be protected against irritation.

"Cristolax" provides an eminently satisfactory lubricant which can be applied with benefit in such conditions. Apart from ensuring soft, easy stools, its bland nature soothes and protects inflamed surfaces, tends to relieve congestion and effectively assists in healing.

"Cristolax" presents pure medicinal paraffin of optimum viscosity in elegant combination with "Wander" Dry Malt Extract. Being entirely free from any oily or disagreeable taste it is easy to administer and its use does not give rise to the unpleasant symptom of "leakage."

# MILTON

**Detergent, Penetrative, Germicidal, Osmotic, Non-toxic,  
LIQUEFACTIVE, Regenerative**

**LIQUEFACTIVE.** A disinfectant which produces an excessive amount of coagulation with proteins and albumens has a tendency to form a protective coating over an affected surface which prevents the penetration of the disinfectant to the point where its action is needed.

In contrast with most chemical antiseptics, Milton does not coagulate proteins, except at full strength. 10% Milton shows no coagulation with saliva or horse-serum. Even the proteins insoluble in water, as myosin and fibrinogen, are readily soluble in Milton.

The qualities of this carefully designed preparation and its superiority over other "hypochlorite" antiseptics—e.g. Dakin's Fluid and Liq. sod. chlorinate—have been clearly demonstrated by special laboratory researches, the results of which have been amply confirmed in practical use. Reports of these researches and a sample of Milton will be forwarded to any medical practitioner on request.

Milton is supplied at a standard strength ready for immediate use, and is stable. It is safe for either external or internal application.

MILTON PROPRIETARY LIMITED, JOHN MILTON HOUSE, LONDON, N 7

URETHRAL bleeding from inflammation or trauma after instrumentation requires prompt and efficient treatment to the satisfaction and detriment of public health.

A 10 per cent solution of Argyrol injected and retained in the urethra for ten or fifteen minutes usually controls all but the most severe bleeding and helps to restore the damaged mucosa to the normal.

We make this statement on the authority of a noted urologist who favoured the method with satisfaction for many years.

## ARGYROL

BY DR. H. VITELLI

It should be remembered that while there are many mild silver proteins there is only one Argyrol—the prototype of them all and it stands in a class by itself *argyrolis* because no other silver product contains

in its chemical and physical state the properties of a similar high quality and stability. Argyrol solution has never been successfully duplicated.

In insistence on having the name ARGYROL on all solution ordered or prescribed will ensure the clinical results you expect.

# OESTROFORM

*In the treatment of Vulvo-Vaginitis*

According to a recent paper on gonococcal vulvo-vaginitis in children (*Lancet*, April 23rd, 1938, p 93) 'the most modern treatment of such cases consists (in addition to local irrigation, vaginal packs, and vulvar sitz-baths) in administration by mouth or by injection of an œstrin preparation

It is stated further (*Lancet*, April 23rd, 1938, p 960) that 'the purulent gonococcal discharge soon gives place to one containing many squamous epithelial cells and Döderlein's bacillus but no gonococci'

The treatment usually recommended consists of the administration of one tablet of Oestroform (1000 I U) four times daily together with the collateral use of one or two Oestroform pessaries daily

# TO REPLACE MORPHIA.....

## 'EUKODAL'

(Dihydrohydroxycodemonone hydrochloride)

A safe and reliable analgesic and sedative, derived from thebaine, and not to be regarded as a morphine derivative. Offers an equal and sometimes greater degree of potency than morphia, with less danger of side-effects and habituation. Approximately twice as potent as morphia, weight for weight, a 1/12 gr 'Eukodal' tablet being equivalent in its effect to a 1/6 gr dose of morphia.

TABLETS of 1/12 gr, AMPOULES of 1/6 and 1/3 gr in 1 c c, and POWDER

## 'EUPACO'

(Eupaverin Compositum)

A powerful and well-tolerated spasmolytic, combining the anti-spasmodic properties of Eupaverin (a more potent and less toxic form of papaverine), atropine, amidopyrine and phenobarbitone. Effective in all spastic conditions of smooth muscle, and may be used to replace morphia in certain cases.

## VITAMIN B<sub>1</sub> B.D.H.

The importance of Vitamin B<sub>1</sub> in metabolic processes is being increasingly realised. At the same time, clinical experience is confirming that the usual dietary is deficient in this important substance. Such minor deficiencies as are commonly met with can be adjusted by the administration of Vitamin B<sub>1</sub> as included in Multivite.

There are, however, certain pathological conditions of fairly high incidence which indicate a more serious deficiency of Vitamin B<sub>1</sub> and require treatment with the pure vitamin in considerably larger doses

than are practicable through the medium of Multivite.

For the treatment of these more serious deficiencies, symptoms of which may include constipation, anorexia, bradycardia and neuritis, Vitamin B<sub>1</sub> B.D.H. is available in the form of solutions—2 mg (1000 international units) per c.c. and 10 mg (5000 international units) per c.c.—for parenteral administration and in the form of tablets—1 mg (500 international units) per tablet—for oral administration.

*Samples of any of the above will be sent on request.*

THE BRITISH DRUG HOUSES LTD LONDON N.1

#### FORMULA

Thyminic Acid	0.10
Hexamethylenetetramine	0.50
Anhydromethylenecitrate	0.50
Hexamethylene Tetramine	2.50
Piperazine Tartrate	0.25
Lithium Carbonate	1.00
Sodium Benzoate	1.00
Effervescent Base	rd 100

#### DIRECTIONS

One teaspoonful to be taken morning and night in a tumblerful of water

*Uralysol*, in addition to being a solvent and eliminator of pathological Uric Acid, is a powerful urinary antiseptic.

Normally there exists in the body a certain quantity of uric acid, which assists general metabolism, and after it has played its part is eliminated together with the normal thyminic acid of the organism. When, however, uric acid is present in excess, the body needs additional thyminic acid to supplement the resultant deficit of this normal solvent of uric acid.

*Uralysol*, by its thyminic acid content, supplies the agent necessary to dissolve excessive uric acid.

The next step is the elimination of this thyminic uric acid which, being in excess of normal, necessitates treatment by an agent capable of enhancing elimination.

*Uralysol*, by its content of hexamethylenetetramine and lysidin, stimulates the organism to eliminate the pathological uric acid already dissolved by its thyminic acid content.

## Pleasure Cruises . . .

3rd March, 1938

Messrs Kaylene Ltd, Waterloo Road, London, NW 2

Dear Sirs

I have to thank you for the samples of KAYLENE and COLONOL LIQUID PARAFFIN, which arrived this morning.

It may be of interest to you to learn that KAYLENE-OL is an admirable prophylactic for the dysenteries and other intestinal infections common in hot countries. I invariably prescribe it to patients who are going for a holiday in the countries around the Mediterranean littoral, or pleasure cruising.

I think it probably acts by preventing injury to the intestinal mucosa in patients who evaporate a lot of fluid from the skin and, in the case of amoebic dysentery, by hindering the *Entamoeba Histolytica* from entering the crypts of Lieberkuhn by occluding them with an oily film.

Patients who use it systematically every day as a prophylactic remain singularly free from the numerous troubles arising from the exuberant bacteriological flora of the intestine which is the rule in hot countries.

I am guided in my opinion largely by personal experience. I have had dysentery seven times and each time was definitely associated with the running short of my usual prophylactic dose. I do not know of anybody ever contracting dysentery while maintaining the regular daily prophylactic dose of KAYLENE-OL.

Yours faithfully,  
Signed

, MD

# Why 'OVALTINE' is Supreme for Quality and Value

*'Ovaltine' provides the Highest Possible Quality  
at the  
Lowest Possible Price*

THE whole Ovaltine organisation at King's Langley Herts is planned for *quality* production. Yet Ovaltine is produced at a price which makes it definitely the most economical in use. This is due to the modern scientific methods of manufacture employed coupled with the world-wide demand for Ovaltine.

Scientifically prepared from finest malt milk and eggs, Ovaltine stands in a class by itself. Although imitations are made to *look* like Ovaltine there are very important differences.

*Ovaltine does not contain any House-  
hold Sugar. Furthermore it does not  
contain Starch. Nor does it contain  
Chocolate or a large percentage of  
Cocoa.*

By reason of its unique composition, exceptionally high quality, and the scientific processes employed the manufacture of Ovaltine involves a large expenditure. Nevertheless because of its unrivalled popularity and large world wide demand it is available at a price which makes it the most economical in use.

Prices in Gr. Britain and N. Ireland 1/1 1/10 and 1/3

4 ozs	-	-	-	1/-
8-ozs	-	-	-	1/9
For dispensing 80 ozs	-	-	-	15/-

**C**OLLOSOL Lacto Magnesia contains 43 grains (10 per cent) magnesium hydroxide in each fluid ounce

It presents the hydroxide in an extremely fine state of sub division—colloidal form—ensuring an even and rapid effect. This is of great value when the product is used as a mouth wash, and penetration to the innermost folds of mucous surfaces and to the interstices of the teeth is desired.

In dental practice and when an alkaline mouth wash is called for, two teaspoonfuls stirred up in a half to one wineglassful of water is effective and refreshing.

Collosol Lacto Magnesia has a pleasant natural flavour and is most economical, both in price and in usage.

## B.D.H. VACCINES

The special rubber-capped 3 c.c. vials in which B.D.H. Vaccines are issued are appreciated by all physicians who have employed them in the course of practice, on account both of convenience and economy. They find that the usual wastage associated with the use of a fresh 1 c.c.

ampoule for each injection in a course comprising from four to six injections is avoided. By the use of B.D.H. Vaccines there is thus effected a saving both in time and expenditure.

The metal dust-cap (which is removed before the needle of the

syringe is inserted through the rubber cap and is replaced after the vaccine has been withdrawn and the rubber cap swabbed with disinfectant) serves to maintain the sterility of the rubber cap, keeping the whole vial ready for use on the next occasion.

*A specimen 3 c.c. vial containing any one of the B.D.H. Vaccines will be sent on request.*

# Disease-emaciation

"EVERY medical practitioner knows how difficult it is to nourish a patient suffering from disease-emaciation. Do we not all recognise the fact that the starving tissues are fed, not by the food swallowed by the patient, but by the amount of nutrient matter absorbed by the gastric and intestinal mucous membrane? If we could ensure the absorption of nutriment into the blood, the problem of nutrition in disease would be reduced to a matter of mere chemistry and mechanical feeding. Judging from clinical results, 'Sanatogen' appears in many cases to possess some power of ready absorbability, without which the richest foodstuff represents simply so much foreign matter in the stomach and intestines. My own experience of 'Sanatogen' is that it stops the diarrhoea—ten or twelve motions a day are thereby reduced to one or two, it stops vomiting, and it improves general conditions and causes the patient to put on flesh."

"NUTRITION IN WASTING DISEASES OF CHILDREN AND ADULTS"  
(*Medical Press and Circular*)

"THIS condition, which results from imperfect digestive or absorptive power, or which may follow stomatitis, pyloric stenosis, deformity of the tongue or palate, tuberculosis or syphilis, is most frequently associated with improper feeding. Fats in such cases are not well tolerated, but the contrary is true with respect to proteids. The use of 'Sanatogen', in these cases, proved so satisfactory that we have been encouraged to try it in other cases of infantile atrophy, and have had almost equally pleasing results in a number of patients suffering from this condition. It is quite apparent that 'Sanatogen' has considerable power in influencing nutrition."

"INFANTILE ATROPHY"  
(*Practitioner*)

"I HAVE before me the records of forty cases fed with 'Sanatogen'. They show, what was obvious to myself and the nurses when watching the cases, that these patients wasted less during the acute stage, and picked up more rapidly during the convalescent stage, than patients who did not have 'Sanatogen'. This fact, indeed, was soon recognised by the ward sister, without my having in any way drawn her attention to it. . . I am firmly convinced that it is a most valuable food for the typhoid patient."

# CRUNCHY FOODS AND THE HEALTH OF CHILDREN

---

The inclusion in every child's diet of a quantity of hard, dry food is regarded as essential by many practitioners. Such food compels thorough mastication, the regular exercise this gives to the jaws is believed to assist their correct development, thus preventing many possible troubles to the teeth in later life.

The importance of instilling the habit of thorough mastication is further stressed because of its value to digestion, to which the practice of swallowing insufficiently chewed masses of food is considered extremely harmful.

Many physicians therefore recommend that growing children should eat crisp Ryvita with their meals. Free samples of Ryvita for distribution to patients will gladly be supplied on request.

# BRIEF BUT POWERFUL ACTION

## *Rapid Recovery*

Pentothal Sodium (Abbott) is a powerful hypnotic of the thio-barbiturate group. Injected intravenously it produces prompt sleep with rapid recovery. Being a non-volatile anesthetic its effects are not entirely controllable but it is so rapidly destroyed in the body that when properly administered in dilute solution by the intermittent method it approaches the minute-to-minute controllability of inhalation anesthetics. Pentothal Sodium has been extensively used experimentally for short operative procedures in which intravenous anaesthesia was more convenient than block or inhalation anaesthesia or where the latter were contra-indicated. It has been reported to be more powerful and rapid in action than other barbiturates to give a smooth and pleasant induction to anaesthesia with better relaxation and rapid recovery and to produce jaundice only rarely. Pentothal Sodium is not recommended for use in major operative procedures requiring prolonged anaesthesia and its use should be undertaken only by experienced anaesthetists or surgeons who have at hand facilities to combat problems involving respiratory depression as well as carbon dioxide and oxygen imbalance. Pentothal Sodium (Abbott) is issued in ampoules containing 0.5 gm and 1.0 gm of the drug together with ampoules of chemically pure water for making solutions. The coupon below is for your convenience in requesting professional literature and reprints.

**Left** —The indigestible casein clot formed by cow's milk with an equal bulk of plain water

**Right** —The finely divided precipitate formed when cow's milk is modified by Robinson's 'Patent' Barley

In infant feeding, unmodified cow's milk tends to form a tough casein clot and is thus liable to cause indigestion. The specimens shown above illustrate the results of an experiment made in our own Research laboratories. They are 'in vitro' reproductions of the 'in vivo' conditions prevailing in an infant's stomach, and they show that the formation of the indigestible clot can be prevented if cow's milk is modified by Robinson's 'Patent' Barley.

# ANTUITRIN-GROWTH

## THE ANTERIOR - PITUITARY GROWTH HORMONE

A separation and purification of the growth hormone of the anterior lobe of the pituitary gland has been effected in the Parke-Davis Laboratories, and the result is embodied in the solution issued under the title "Antuitrin-Growth". This preparation is a relatively stable solution of the growth hormone, from which other substances such as the gonadotropic and thyrotropic hormones and inert protein matter have been substantially eliminated.

Standardization of Antuitrin-Growth is effected by biological assay on female rats. A unit of the growth hormone is defined as the minimal daily amount which, when injected intraperitoneally into a mature female rat, will cause an average daily increase of 1 per cent in bodyweight over a period of at least ten days. Antuitrin-Growth contains 20 rat-units per c.c.

Details concerning Antuitrin-Growth and its clinical applications in the treatment of endocrine dwarfism associated with hypofunction of the anterior lobe of the pituitary gland will be furnished on request. Issued in rubber-capped vials of 20 c.c.

## TYPHOID FEVER ITS CLINICAL ASPECTS\*

BY

SIR WILLIAM WILLCOX, K.C.I.E., C.B., C.M.G., M.D., F.R.C.P.

Consulting Physician to St. Mary's Hospital Senior Physician, the London Fever Hospital

The recent outbreaks of typhoid fever notably in the Bournemouth district in 1936 and in the Croydon area in 1937 have aroused renewed interest in this disease which in recent years had become comparatively uncommon. The typhoid bacillus still breeds true and while the outbreaks may differ somewhat in the clinical syndrome of symptoms the specific organism maintains its virulence and the percentage mortality in the recent outbreaks remains high being about 10 per cent. The public who during recent years have grown accustomed to a freedom from outbreaks of a disease which thirty years ago was extremely common have not unnaturally displayed surprise and alarm.

The statistical figures of the Registrar General show a remarkable fall in the death rate (see Table I). In 1893

TABLE I—Enteric Fever Statistics Typhoid—Paratyphoid Fever Death Rate per Million England and Wales

Year	Rate	Year	Rate
1893	30	1931	6
1905	101	1932	6
1913	41	1933	5
1923	14	1934	4
1925	9	1935	4
1930	7	1936	6

this was 230 per million in 1903 it was 101 in 1913 it was 41 and since 1931 the annual death rate per million has not exceeded 6. The occurrence of outbreaks in spite of the great advances in sanitary science shows the necessity for a never ceasing vigilance to prevent the possibility of infection.

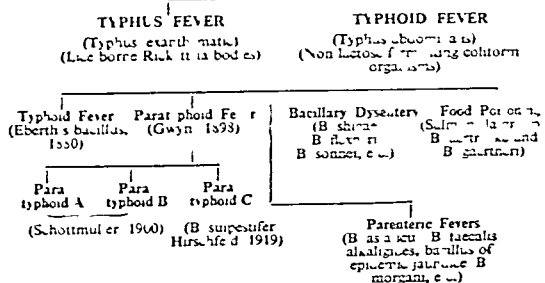

### Historical

Typhoid fever is so chameleon like in its clinical manifestations that in considering the diagnosis of a case of simple continued fever one should bear in mind the many varieties of disease which may give rise to this. The outlook of the physician should be as broad as possible and before arriving at a diagnosis of typhoid fever other possible causes must be excluded and the clinical diagnosis clinched by the results of appropriate laboratory investigations. A review of the differentiae of the simple continued fevers is of importance because all of these need remembrance when an undiagnosed case is first seen (see Table II).

Up to 1849 the simple continued fevers in this country consisted of typhus and typhoid fever and both were commonly called typhus fever. Sir William Jenner, A. P. Stewart and others differentiated typhoid fever clinically but it was not until 1880 that the specific bacillus was

discovered by Eberth. At that time many varieties of enteritis with continued fever were included under the term typhoid fever.

TABLE II  
TYPHUS FEVER  
(Simple continued fever of Great Britain up to 1849)

In 1898 paratyphoid fever was differentiated by Gwyn of the Johns Hopkins Hospital. In 1900 paratyphoid fever was differentiated into the two types A and B and in 1919 a further type paratyphoid C was described by Hirschfeld. This latter organism being identical with the *Bacillus supestifer* (hog cholera).

The non-lactose fermenting coliform organisms have during the last forty years been further differentiated into

(i) The parenteric group which includes the *Bacillus jaecalis albidus*, *B. asiaticus*, the bacillus of epidemic jaundice *Bacillus morganii* etc.

(ii) The dysentery group which includes Shiga's bacillus, Flexner's bacillus (five strains) and Sonne's bacillus etc.

(iii) The Salmonella group of which *B. aertrycke* and *B. enteritidis* of Gaertner are the two chief types.

All of these organisms may give rise to a continued fever the clinical symptoms of which may so closely resemble true typhoid fever as to be almost indistinguishable from it except by bacteriological and pathological tests.

In the Dardanelles campaign in the latter half of 1915 a great number of enteric cases were treated at Mudros which was the nearest hospital base. It seemed clear from the clinical features that the cases diagnosed as enteric were not all true typhoid fever. A careful investigation of these cases by Captain R. G. Archibald (now Colonel Sir Robert Archibald) and myself showed that of the cases diagnosed as enteric fever the majority were paratyphoid fever the latter being 6+ times as

\*Address to the Croydon Division of the British Medical Association March 22 1938

CHART A—Typhoid fever, severe relapse after inoculation with prophylactic vaccine (St Mary's case)

CHART D—Fever after inoculation, headache, rigor, enlarged spleen, etc (War case)

CHART E—Paratyphoid A after inoculation on March 16, headache and enlarged spleen on March 20, and death on March 22, 1916 (War case)

CHART B—Case 7 Typhoid fever severe and prolonged course following mild early symptoms death

CHART C—Fever after second inoculation, enlarged spleen headache, etc, on March 23, 1916 (war case) BF = Blood film no para sites seen BC = blood culture sterile, 24 to 48 hours

temperature will immediately follow even a small dose of vaccine and the toxic symptoms are much increased. Chart A shows one example of such ill effect after the original attack of fever had subsided. It has been my experience not only with typhoid fever but in the case of infection with other of the non lactose fermenting organisms such as paratyphoid parenteric and food poisoning that very adverse results are obtained by the administration of vaccines in the acute stages of the illness.

### Serum Treatment

Serum from convalescent patients has been administered but the results have not been of notable benefit. The use of a foreign serum appears to be dangerous in that the immunity may be disturbed. In one case under my care the administration of a small dose of polyvalent anti streptococcal serum was followed by severe haemorrhages from the bowel and nose with fatal results.

Valuable research work is being carried out by Dr A Felix who has demonstrated the presence of the Vi and O antigens in *B. typhosus*. Antisera have been prepared from the horse and these have been shown to be of value in typhoid infections in animals (mice etc). At the present time the value of these antisera in human typhoid is still *sub judice* and there is no evidence that the mortality is reduced by their use. The danger of a prejudicial disturbance of the delicate mechanism of immunity in the human subject appears to outweigh the possibility of benefit.

## Blood Transfusion

This has been advocated on the Continent and in certain cases such as severe anaemia in which the acute phase of the toxæmia has subsided it may be of undoubted value. In the stage of acute toxæmia there is danger of the disturbance of the immunity balance and a simple transfusion with normal saline with or without glucose

Chart F—Typhoid fever mild (Bournemouth 1914)

would appear to be safer. In one severe acute case (Case B) blood transfusion was followed by acute streptococcal toxæmia and a fatal result.

### Prophylactic Inoculation during an Epidemic

Prophylactic inoculation has become definitely established. The experience during the great war and in our army since the South African War has proved its undoubted value. It must be admitted however that where there is a probability that infection has already been incurred prophylactic inoculation may precipitate an attack of typhoid fever and in such cases would be best avoided.

Three cases came to my notice during the war (see Charts C D E) in which inoculation was immediately followed by an attack of enteric fever. In one instance where two young children had been together at Bourne-mouth one of whom developed a mild attack of typhoid fever (Chart F) the administration of T.A.B. vaccine to the other was followed immediately by a very severe attack of typhoid fever (Chart G). There appeared to be no doubt that the inoculation disturbed the immunity balance and precipitated an attack which might have been avoided (Charts F and G).

CHART G—Typhoid fever severe immediately after inoculation  
(Bournemouth case)

CHART H—Case 11 Typhoid fever  
profound toxemia death

During an epidemic where there is a probability that infection has actually occurred prophylactic inoculation would be best withheld until the incubation period has been passed, otherwise, generally speaking, prophylactic inoculation is advisable.

In conclusion there is no disease in which the motto "safety first" is more applicable than in the case of typhoid fever.

**Case 1** (E. H. S., a man aged 58)—Onset occurred on October 20, 1937, with malaise and abdominal discomfort. There was an irregular pyrexia of mild degree ( $98^{\circ}$ – $101^{\circ}$ ) up to November 9. Agglutination reaction 1/50 *B. typhosus* November 1. The patient was admitted to the London Fever Hospital November 9, 1937, temperature  $99.5^{\circ}$ , pulse 80. The temperature ranged between  $97^{\circ}$  and  $102.5^{\circ}$  up to November 20. It was normal from November 20 to December 18, then a relapse occurred, with a temperature of  $99^{\circ}$ – $102^{\circ}$  up to December 31. It was normal again from December 31, 1937 to January 9, 1938. From January 9 it ranged between  $101.5^{\circ}$  and  $96^{\circ}$ . Death occurred on January 24, 1938. This case was characterized by severe and persistent toxæmia with comparatively slight pyrexia and absence of delirium until the last five days of the illness. On December 30, 1937, a local slight perforation occurred in the right iliac region, the symptoms of which cleared up in five days with treatment. Pain in the left leg over the tibia occurred on December 20, due apparently to periostitis. On January 10, 1938, pus was found over the left tibia by exploration, and on January 11 a subcutaneous abscess over the left tibia was opened and drained. *B. typhosus* being found in the pus. Pyelitis occurred on December 18 *et seq.* the urine containing pus and albumin and *B. typhosus*. Myocarditis was present during the last three weeks of the illness. On three occasions there was a sudden drop in temperature, with rapid feeble pulse and cardiac collapse. Vomiting due to toxæmia occurred several times during the last three weeks. On January 11, 1938, the liver became enlarged, and toxic jaundice in mild but definite degree persisted till the end.

**Case 14** (P. T., a woman aged 43)—The patient was admitted to the London Fever Hospital on November 13, 1937, with a history of malaise and mild fever for the previous twelve days. Agglutination reaction +1/1000 *B. typhosus*. The temperature reached  $102.5^{\circ}$  on November 16, 17 and 18 and subsided to normal on November 24. A relapse occurred on November 25 with intermittent pyrexia up to January 24, 1938, after which date the temperature remained normal and the patient made a good recovery. Melaena occurred on December 3, 1937. On December 25, 1937, there was a rigor due to pyelitis. The urine contained pus and albumin and *B. typhosus*. A rigor with sudden fall of temperature from  $103^{\circ}$  to  $97^{\circ}$  occurred on December 26 and 28, and January 1, 2, and 6, after which date the temperature became intermittent and gradually subsided. Hexamine salicylate was given intravenously daily for twelve days with benefit; afterwards hexamine was administered by mouth.

**Case B** (a man aged 63)—Onset occurred on February 5, 1931 with typical symptoms. The temperature ranged up to  $103^{\circ}$  and gradually fell to normal on March 4. On February 15 *B. typhosus* was found in the stool. Agglutination reaction +1/1000. On February 18 acute distension of gall-bladder occurred with collapse. This cleared up quickly after atropine hypodermically. The temperature was normal from March 4 to March 15. During this period severe toxæmia with delirium occurred. On March 15 the temperature rose and became remittent in character. During the last five days it reached a height of  $105^{\circ}$ . On March 24 a blood transfusion was followed by some improvement. A second transfusion on March 25 was followed by a rigor and temperature rising to  $105.6^{\circ}$  on the following day. Streptococci were found on blood culture on March 25—probably a terminal auto-infection. Death occurred on March 27, 1931.

This case was characterized by a continuous acute toxæmia which persisted although the temperature was normal for the

eleven days previous to the relapse. During the period of the relapse the symptoms of toxæmia became greatly increased—due, no doubt, to a secondary streptococcal infection.

My thanks are due to Dr. G. Lewin of Croydon for kindly giving me notes of cases under his care, also to my colleagues Dr. C. E. Lakin for the use of his case notes.

I am greatly indebted to Dr. Richard Massingham, medical superintendent of the London Fever Hospital, for providing me with notes and charts of all the recent cases treated at that hospital, also to my son, Dr. Philip Wilcox, for help in the copying of charts.

[The blocks for Charts A, F and G have been kindly lent by the Medical Society of London.]

## PROPHYLACTIC USE OF ANTI-TYPHOID SERUM IN A LOCALIZED OUTBREAK

BY

JAMES FENTON, M.D., M.R.C.P., D.P.H.

Medical Officer of Health Royal Borough of Kensington

AND

CHARLES P. HAY, M.D., M.R.C.P., D.P.H.

Deputy Medical Officer of Health Royal Borough of Kensington

During October and November, 1937, there occurred in Kensington a small outbreak of typhoid fever involving five cases.

### History of the Outbreak

The first case was that of Mrs. S., who fell ill on October 9, 1937, and was sent to a general hospital on October 16, by a private practitioner, with a diagnosis of bronchitis. On October 26 she was transferred to a fever hospital as a suspected case of typhoid fever. This information was reported to the Public Health Department on October 27, and that day the rooms occupied by Mrs. S. and her family were disinfected. The family consisted of Mr. and Mrs. S. and six children, the eldest of whom was 14 years of age. Two other families also occupied rooms in the same house—the N family, consisting of Mr. and Mrs. N. and two daughters aged 14 and 12 years, and another family consisting of three persons. The house was of the three storied tenement type, there being two water closets, which were used indiscriminately by all the occupants.

On November 17 the same practitioner was called in by the N family, and he found both Mr. and Mrs. N. very ill. He diagnosed typhoid fever in the case of Mr. N., who was removed to a fever hospital, and died on Saturday, November 20. In the case of Mrs. N. he did not suspect typhoid fever, but recommended her transfer to a general hospital. This offer was refused.

On Thursday, November 18, the Public Health Department heard that Mr. N. had been removed to hospital suffering from typhoid fever, and when inquiries were made at the home it was learnt that Mrs. N. had died there during the night. A post mortem examination was arranged for the same day, and this was performed by Sir Bernard Spilsbury. The cause of death was peritonitis due to perforation of a typhoid ulcer. It was estimated from the condition of the organs, and from the history, that the case was then of about three weeks' duration. That day all the occupants of the house were examined by the deputy medical officer of health, one case

Mary N. aged 14 years was found to be suffering from typhoid fever and was transferred to a fever hospital. The duration of the disease in her case was estimated to be about twelve days.

All the home contacts and Mrs. B., a married daughter of Mrs. N. who lived in a house in the same street and who had also been in close contact with the N. family, were visited daily by the sanitary inspector, and were reported to be in good health. On November 21 the deputy medical officer of health visited all the contacts, including Mrs. B. and they reported well. A hint from another contact to the effect that Mrs. B. was not well led him to insist upon making a clinical examination. He found her to be suffering from typhoid fever of about fourteen days duration. Her reason for not admitting to any symptoms—which although mild she had nevertheless guessed were due to typhoid fever—was that she wanted to go to her mother's funeral.

Mrs. B. her husband a child aged 5 years and a baby aged 3 months lived in a house similar in type to that occupied by the other patients. There were two other families in the house numbering twelve persons. In both houses it was the common practice to pass food from one family to another and there were abundant opportunities for infection to have passed from the various patients to the contacts in other families both by means of their food supply and by means of the lavatories which were in common use.

The situation on November 21 1937 was that there had occurred in two houses five cases of typhoid fever, two of which had proved fatal. Twenty-six intimate contacts were involved in the two houses whilst a further family consisting of man, wife and three children were also involved, the wife—another married daughter of Mrs. N.—and her family having visited the Ns. house and had meals there during the previous week.

#### Prophylactic Dose of Serum for Contacts

The question now arose as to whether some form of immediate protection could be given to these thirty-one contacts. T.A.B. vaccine was considered but was rejected in view of the fact that some of the contacts might in fact be incubating the disease. The use of anti-typhoid serum as prepared at the serum department of the Lister Institute by Felix's method was then discussed. There was no record of the use of this serum for prophylaxis in the past but as the contacts were all known to the Public Health Department were localized and had all been in intimate contact with the patients and therefore subjected to grave risk of infection and might in fact be incubating the disease anti-typhoid serum was given in the belief that it would confer immediate protection. This was offered to and accepted by all contacts. The dose given was 10 ccm to each adult and 5 ccm to each child administered by the intramuscular route. The injections did not produce any symptoms of serum sickness or other unpleasant reactions.

No cases of typhoid fever occurred among these contacts. This fact is not in any way considered a proof that the serum did actually prevent the onset of typhoid fever in any of these persons; the present report of the outbreak is intended more to illustrate the type of circumstance in which inoculation with anti-typhoid serum is in our opinion the correct course to pursue—a course that might well be adopted in similar circumstances in the future.

## NOTE ON THE PREVIOUS COMMUNICATION

BY

A. FELIX, D.Sc.

*Member of the Scientific Staff, Lister Institute, London*

The administration of a prophylactic dose of anti-typhoid serum to the group of persons referred to in the communication by Fenton and Hay (see p. 1090) provided the opportunity for estimating the concentration of the circulating antibodies that had been passively transferred with the prophylactic serum. It was thought that some indication might be obtained in this way of the effective dose of anti-typhoid serum for prophylactic use. Such information would be helpful because doubts had arisen as to whether the dose recommended by the serum department of the Lister Institute was not too large. The prophylactic dose for an adult had been arbitrarily chosen as one third of that recommended for the treatment of typhoid patients—namely one dose of 35 ccm of serum injected intramuscularly, three doses of 35 ccm are recommended for the treatment of adult cases of moderate severity; the dosage for children is correspondingly smaller.

#### The Serum used in the Outbreak

The anti-typhoid serum used by Fenton and Hay was derived from two different batches. The titres of the various antibodies present in the serum from the two batches are shown in Table I.

TABLE I

Anti-typhoid Serum	Titre of Antibodies Estimated by Agglutination		
	H	O	Vi
Batch No. 11 (issued March 1936)	200,000	100,000	700
Batch No. 19 (issued September 1937)	20,000	100,000	3,000

When the serum was used for the inoculation of the group of contacts the difference in the concentration of the antibodies in the two batches was unknown to Fenton and Hay. The two sera were therefore given in equal quantities—namely 10 ccm to each adult and 5 ccm to each child under 14 years; the number of the batch from which the dose had been given was recorded in each instance. Two days after the administration of the anti-typhoid serum samples of blood were taken from nineteen persons out of a total of thirty-one contacts who had been inoculated. The No. 11 serum had been given to eight of these persons (three adults and five children) and the No. 19 serum to eleven persons (eight adults and three children). The antibody content of the blood serum from the nineteen contacts was estimated according to the same technique as that employed in the examination of the therapeutic horse serum and the result is shown in the following table.

TABLE II

Anti-typhoid Serum Injected	Average Titre of Antibodies present in the Serum from 17°C. 12 Hours after the Administration of the Prophylactic Dose			Average Calculated from
	H	O	Vi	
Batch No. 11	200	200	<5	3 observed titres
Batch No. 19	0	200	<5	11 observed titres

When the figures shown in Table II are compared with the corresponding figures recorded in Table I it is seen that the H titres of the sera from the contacts were 1,000 times lower and the O titres 500 times lower than the titres of the two therapeutic sera that had been used for the injections. If account is taken of the fact that the titre of the natural H antibody in normal human serum is extremely low, whereas the O titres for the sensitive typhoid strain 0901 often reach a dilution of 1 in 50 or 1 in 100, it may be concluded that the H titres give the correct measure of the degree of dilution of the passively transferred antibodies. Judging from the dilution factor, one could not expect to demonstrate the Vi antibody in the serum from the inoculated persons even in a dilution of 1 in 5, which, according to my experience, is the limit of the natural Vi agglutinin in human serum. Actually only two out of the nineteen sera tested produced marked Vi agglutination in a dilution of 1 in 5. One of the two persons who gave a positive Vi reaction was re-examined twelve days after the administration of the prophylactic dose. The Vi reaction was then negative in the dilution 1 in 5, and the H and O titres had fallen to less than half the values that had been established two days after the inoculation.

#### Comments

It is not suggested that these observations indicate that the prophylactic doses administered by Fenton and Hay were too small. The results of experiments in mice show clearly that the potency of the Vi antibody in protective action is very striking when contrasted with the comparatively low titre of its *in vitro* action in agglutination tests. It is quite conceivable that adequate protection may be afforded when the circulating Vi antibody is not demonstrable by agglutination even in the undiluted serum. However, in the absence of adequate data relating to the results of the prophylactic use of the serum in man it would appear to be inadvisable to reduce unduly the amount of the specific antibodies that are injected.

The titre of the Vi antibody in the concentrated anti-typhoid serum as issued at the present time is 1 in 3,000. Until serum with a considerably higher content of this antibody can be prepared the following recommendation seems to be justified for prophylactic use: one intramuscular dose should be given, and this should lie between the limits of one-sixth and one-third of the full curative dose, which is 99 ccm for an adult and proportionately less for a child. When deciding on the dose to be administered account should be taken of the degree of risk and of the length of exposure to the infection.

The Association of Special Libraries and Information Bureaux (31 Museum Street London, W.C.1) held a luncheon at the Cafe Royal on April 27 at which over eighty people were present. The president, Sir Harry Lindsay, Director of the Imperial Institute, spoke of the three stages of science: first scholasticism dominated by the great scientists; then the period of the authoritative textbooks; now the era of the individual specialist. The results of modern scholarship were scattered in innumerable technical journals, and in order to keep abreast search must be made over a very wide field. The same was no less true of other spheres of knowledge.

ASLIB was therefore formed to act as a guide to specialist sources of information. Sir Clement Hindley said that members of the Association were eager to facilitate the dissemination of knowledge, and Sir Ian MacAlister spoke of ASLIB as a valuable and essential part of the great movement to make the instruments of civilization work.

## OUTBREAK OF SONNE DYSENTERY DUE TO CONSUMPTION OF MILK

BY

G. K. BOWES, M.D., M.R.C.P.

Medical Officer of Health Bedford

The following account of an outbreak of Sonne dysentery due to milk may be of interest.

#### Course of Outbreak

On January 5, 1938, information was received in the Public Health Department, Bedford, to the effect that five persons employed in a neighbouring office, all of whom had drunk raw milk there on the morning of Tuesday, January 4, had been taken ill with diarrhoea and vomiting on the evening of the same day or early the following morning. Since all members of the office staff came from different homes, the milk drunk appeared to be the only food common to the individuals concerned. Moreover, all those who partook of the milk were affected, and none of the office staff who had not drunk it had had similar symptoms. The milk was delivered daily by a retailer who obtained all his supplies from a farm about seven miles away, the retailer's dairy being the only one in Bedford to receive this milk. It arrives in churns, and is distributed raw to the consumers, some in bottles and some "loose". The bottling is done by the retailer. No other persons but the retailer and his wife, who is employed mainly in the shop connected with the dairy, lived on the premises or worked in the business. The retailer was interviewed by a member of the sanitary staff on the morning of Wednesday, January 5, and stated that he had had no complaints from his customers of any illness caused by the milk. This statement seemed at first to throw some doubt upon milk as the source of the illness.

Samples were, however, obtained from milkings of the evening of January 5 and the morning of January 6 and sent to the County Medical Officer, Dr C. G. Welch, in whose area the farm is situated, with a suggestion that a veterinary inspection of the cows might also be made. This veterinary inspection was undertaken, with negative results. At the same time a physical examination of samples showed that the milk was "clean". The County Medical Officer had meanwhile ascertained that another customer in the town had suffered from similar symptoms. On January 7 he obtained a sample of milk as delivered and still sealed, at the house of this customer, and sent it to the Ministry of Health for examination.

On the same day, in a telephonic communication, D. Seymour of the Ministry of Health suggested that if information might be obtained by house to house inquiry among the customers of the milkman. A list of the names was accordingly secured. A preliminary inquiry in the evening of the same day showed that in four of the six houses then visited one or more persons had suffered from similar symptoms. As in the original cases, the symptoms occurred on the evening of Tuesday, January 4, and the morning of Wednesday, January 5. The original cases the milk supply had been stopped at the occurrence of symptoms, but in the households visited no suspicion attached to milk, and members continued to drink it. It therefore appeared likely from preliminary investigation that any infection of the town had been limited to one day—namely, Tuesday, January 4. Though this presumption was subsequently found to be erroneous it was at the time decided, on the evidence available, not to take steps to stop the milk supply.

On Saturday January 5 all households supplied with milk by the retailer were visited by the sanitary staff and inquiries made as to any illnesses with similar symptoms. In all 106 households were visited and it was found that in fifty-nine of them one or more members had suffered from the symptoms in question. The illness occurred alike among those who had had bottled and those who had had local milk. The date of onset of the earliest symptoms in the households is given in the following table.

Monday January 3	2
Tuesday 4	25
Wednesday 5	20
Thursday 6	7
Friday 7	5

Among an estimated number of 224 persons in the households investigated ninety-six or 43 per cent. suffered from symptoms. From the time distribution of the cases the opinion though erroneous appeared to be confirmed that any infection of the milk was limited to one day. Hence it was still decided to take no action to stop the supply.

Specimens of faeces had been obtained from the original sufferers on January 7 and subsequent days and sent to Dr Scott of the Ministry of Health pathological laboratory for examination. On January 10 a report was received from Dr Scott stating that two out of the five specimens showed the presence of dysentery bacilli of Sonne type and that the same bacillus had been isolated from the sample of milk taken on January 7. It appeared quite clear therefore that the outbreak was one of Sonne dysentery and was due to the consumption of infected milk. It also appeared that this milk was still infectious at least as late as the time when the sample was taken (January 7).

In view of this additional and positive information it was decided to stop the milk supply under the power given by the Milk and Dairies Order 1926 till an improvised pasteurizing plant could be installed. With the co-operation of the Bedford Gas Company working in conjunction with the sanitary inspectors such a plant was put into action on the evening of Monday January 10 and it was possible to resume the ordinary milk supply after pasteurization on the following morning. Pasteurization was made a condition of permission to continue the supply of milk until it should have been proved that it no longer contained discoverable dysentery bacilli and that all those handling it at any stage were free from dysentery bacilli and until the conditions at the farm were satisfactory from the point of view of possible milk infection.

In the endeavour to trace the source of the now definitely known infection inquiries were made as to the health of all those who came in contact with the milk. In the course of the preliminary inquiry on January 7 it had already been ascertained that neither the retailer nor his wife the only two persons concerned in handling the milk after delivery to the dairy in the borough had at that time had symptoms. Specimens of faeces were now obtained from both these individuals and sent to the Ministry of Health. At the same time Dr W. K. Parbury, medical officer of health for the Bedford Rural District in which area the farm is situated made inquiries as to the health of those persons handling the milk in the course of its production and transit and obtained specimens of faeces. He also made inquiries at some forty houses to which milk from the farm is delivered by the farm milk lorries before they come into the borough and found that no household had been affected with dysenteric symptoms (with the exception of one patient who had had diarrhoea accom-

panying a definite attack of pneumonia obviously unconnected with the milk). This distribution of cases seemed to make it reasonably clear that the milk had been infected in the town and not on the farm or in the course of conveyance to the town. Reports received from the Ministry of Health showed that the faeces were negative in the case of all persons handling the milk with one exception—namely that of the retailer. This fact however for reasons to be stated cannot be taken as confirming the view formed on other grounds that the milk was infected in the borough.

It has been mentioned that on Friday January 7 the retailer stated that he had not had the symptoms in question. After the receipt of the report on his faeces he was again interviewed and he then said that on January 9 he had suffered from toothache and had drunk milk largely in place of his ordinary food. On the same day he had an attack of diarrhoea. This fact renders it rather more probable that he was himself infected by drinking the milk than that he was the original source of the infection. In consequence of the report received the retailer was on January 15 the date of the receipt of the report prohibited under the provisions of the Milk and Dairies Order 1926 from handling milk or milk vessels till he should be proved free from dysentery bacilli.

The medical officer of health of the rural district carried out at the farm investigations into the water supply from which the cows drank and to which they had access. Normally the cows drank from a trough fed by rain water from the roof of the farm buildings but when this was exhausted they drank from a pond into which they were able actually to enter with the possibility of contamination of their udders. Samples for bacteriological examination were taken both from the trough and from the pond. The first reports on these samples stated. This water is very badly contaminated with intestinal organisms. The *Bacillus coli* are of the faecal type. Organisms of the dysentery group are present but I have been unable to determine which variety without agglutination tests employing specific sera for each form. Subsequent tests of samples of the water with a view to determining the nature of the dysentery bacilli failed to reveal their continued presence. Steps were taken to have the pond fenced off so as to prevent the cows from entering the water though they were allowed to drink from this when the rain water trough was exhausted.

Subsequent specimens of faeces from the retailer proved negative and after the third negative report on January 27 he was permitted to resume handling of milk and vessels. On the receipt of a report from the medical officer of the rural district to the effect that the suspected pond had been fenced off and other minor requirements carried out the retailer was released from the obligation to pasteurize.

No further cases of illness came to light among the customers of the retailer after the systematic inquiries on Saturday January 8. It will be seen that the source of infection of the milk remains obscure.

#### Symptoms

The symptoms in most cases were mild and consisted of abdominal pain, vomiting and diarrhoea for twelve to thirty-six hours. In only a very small proportion of cases was medical advice sought and in only a few cases was passage of blood and mucus in the faeces mentioned. In a few instances the diarrhoea persisted for some days and was accompanied and succeeded by a period of weak-

ness The period between consumption of milk and onset of symptoms was twelve to twenty-four hours in those cases where this could be determined

#### Additional Inquiries

On January 11, when the cause of the outbreak first became clear, all the medical practitioners in the town were informed of the facts and were asked for information as to any further cases which might come to their knowledge. Inquiries were also addressed to the larger local works.

Investigations as to the food and milk supply were undertaken in all cases reported—a comparatively small number—but it was not possible to determine that any further supply of milk or other article of food had been infected.

#### Precautionary Measures

In view of general statements from medical practitioners to the effect that a large number of sporadic cases with similar symptoms had occurred recently in the town, it was at first considered a possibility that other milk supplies might have become infected, and therefore consumers were advised through the Press to boil all their milk. When further investigation failed to reveal any common source of cases other than the one already known it was decided that this precaution might be discontinued.

#### Comments

Dysentery, as is well known, has been widely prevalent throughout the country in recent months, and this has generally been due to the Sonne bacillus. During the weeks ending January 8, 15, 22, and 29 the number of cases notified in England and Wales was 256, 256, 291, and 250, respectively. Dr A. A. Jubb of the Ministry of Health in a communication states as follows:

It is a reasonable conclusion that this outbreak was milk-borne although the mode of infection of the milk has eluded investigation. The detection of the Sonne bacillus in milk has not previously been reported, and the occurrence is therefore of importance for our records.

You will be interested to know that we have received several reports of very full and even laborious inquiries made by medical officers of health into the origins of outbreaks of dysentery during the recent prevalence, but so far nothing tangible has resulted, except that in two instances an article of food was found to be infected with Sonne bacilli. In a few institutional outbreaks, however, it has been possible, owing to the circumstances of a closed community, to trace with a fair degree of certainty the course of a Sonne infection through an article of food, but bacteriological confirmation has been lacking.

In reviewing the course of the outbreak it is easy to see that several mistakes were made. Some of these were perhaps inevitable at the early part of the investigations, when knowledge was incomplete, and some, with the experience gained, might be avoided in a future outbreak. In the first place, at the outset it would have been wiser to suspect an illness of human origin rather than some toxic condition of the milk as the result of possible illness of the cows, which was at the first in my mind. There was at the time, however, nothing to point specially to dysentery, nor did I realize that this illness had so short an incubation period. Secondly, the fact that nearly all the cases would have remained undiscovered if a house-to-house inquiry among all consumers had not been made shows that it is useless to rely upon a statement from the milkman as to any illness among his customers, even if

this had been widespread. In fact, had it not been for the chance information received from a neighbouring office the outbreak might have been undetected, though probably this would have made no difference to its course. Again, it is difficult to say whether it was sound judgment to determine not to stop the milk supply on the evidence available at the time and before definite infection of the milk was known. I should always hesitate to take this action unless there was good evidence that milk had caused, and was continuing to cause or to be likely to cause, serious illness among consumers. As it still appears probable that the retailer himself became infected after the onset of the outbreak, I am of the opinion that there was no reason to prohibit him from taking part in handling milk or vessels at an earlier stage than was in fact done.

#### Summary

- 1 An outbreak of Sonne dysentery due to drinking milk is described.
- 2 Fifty-nine out of 106 households, or ninety-six among 224 individuals (estimated), were affected.
- 3 The incubation period was usually twelve to twenty-four hours.
- 4 Symptoms as a rule lasted twelve to thirty-six hours.
- 5 Sonne dysentery bacilli were isolated from faeces of some of the patients and from the milk itself.
- 6 The actual source of infection of the milk remains untraced.

## THE GONADOTROPIC ACTIVITY OF THE ANTERIOR PITUITARY GLAND IN RELATION TO INCREASED INTRACRANIAL PRESSURE

BY

W. R. HENDERSON, F.R.C.S.

Neurological Surgeon, General Infirmary at Leeds

AND

I. W. ROWLANDS, Ph.D.

National Institute for Medical Research, Hampstead

It is known clinically that a considerable increase in the intracranial pressure, in cases of cerebral tumour, may lead to irregular and even complete cessation of menstruation. This effect is presumed to be due to mechanical compression of the pituitary gland. An investigation of a single case of increased intracranial pressure during pregnancy showed that there was a notable decrease in the hormone content of the placenta and urine (Henderson and Robson, 1936). This result led us to investigate the effect of increased pressure on the amount of gonadotropic hormone in the pituitary of men and non-pregnant women. The results obtained relative to increased pressure are inconclusive, but interesting observations have been made on the pituitaries from cases with normal intracranial pressure, which served as controls to the series.

#### Material and Methods

In all, 109 human pituitary glands were assayed for gonadotropic activity. Fifty-seven of the glands were from patients (twenty-eight men and twenty-nine women) with normal intracranial pressure who died at the St. Mary's Hospital, Queen Square, from a variety of non-neurological diseases other than acute infection.

remaining fifty two patients (twenty eight men and twenty four women) all died from the effects of cerebral tumours (without operation) which had produced an increased intracranial pressure of varying duration. The intracranial pressure in the majority of them as measured by lumbar puncture was 250 to 400 mm of water the normal pressure being 100 to 120 mm.

The pituitary gland was removed at necropsy and the anterior lobe dissected, weighed, desiccated in acetone for forty eight hours and subsequently dried in a current of hot air. No attempt was made to prepare a purified extract containing the gonadotropic hormone. For assay the acetone dried tissue was separated from the sheath of connective tissue ground to a fine powder and suspended in water made slightly alkaline with NaOH. Nearly all of the tissue goes into solution under these conditions. The extract was then adjusted to pH 7.5 and tested on immature rats. Groups of ten rats 40 to 50 grammes in body weight were injected subcutaneously once daily for five days and killed twenty four hours after the last injection. The ovaries and uterus were dissected, fixed in Bouin's fluid overnight and weighed afterwards from 70 per cent alcohol. In order to have a standard by reference to which the individual pituitaries could be compared a mixed sample of acetone desiccated anterior pituitary powder (AP 47) from nine men and five women whose ages ranged from 20 to 65 years was made. The dry powder from these fourteen glands had a total weight of 0.82 grammes.

A dose-response curve was then constructed for the capacity of this preparation to stimulate the ovaries of the immature rat. This curve is shown in Fig. 1 of the article by Boycott and Rowlands at page 1097 of this issue. From the response evoked by this mixed powder it was found that there was sufficient activity in most pituitaries to carry out individual assays using a group of five rats by the above method. There was not however enough material in the pituitary of very young children to assay each one separately, so a number of these glands were grouped according to age and assayed together. The amount of each pituitary required to give a significant response measured by ovary weight was then compared with the amount of the standard preparation necessary to give the same response. From this comparison the activity of each gland was expressed as a percentage of that of the standard.

#### Gonadotropic Activity of the Human Pituitary under Conditions of Normal Intracranial Pressure

The type of response produced in the ovary of the immature rat by human pituitary extract is qualitatively similar to that produced by extracts such as those from horse pituitary and pregnant mare serum which contain a highly effective gonadotropic complex. It contrasts strongly with that produced by extracts of human pregnancy urine and human pregnancy serum (Boycott and Rowlands page 1097 of this issue) which are capable of evoking only a limited response of the rat ovary. The gonadotropic activity of the normal adult human pituitary when tested on immature rats is also quantitatively much greater than that of any other species so far examined. Hill (1933) found a pronounced species difference in the gonadotropic activity of the pituitary tested by the production of ovulation in oestrous rabbits and extracts of horse pituitary proved to be the most active of the species which he examined. One human pituitary from a man aged 64 assayed by Hill showed much less activity than

the pituitary of most of the domestic animals used in experimental work. The activity of the pituitary of men of this age however when tested by the increase in weight of the ovary of the immature rat as in the experiments here recorded is about ten times as great as that of any other species so far examined.

From Fig. 1 it is seen that in both sexes the content of gonadotropic hormone in the pituitary increases with age. During early childhood the pituitary contains only small amounts of the hormone.

FIG. 1.—The gonadotropic activity of the pituitary of men and women with normal intracranial pressure. The women are classified with regard to the occurrence of menopause. Activity is expressed as a percentage of that of the standard preparation.

The activity of a group of seven pituitaries from female children up to 1 year was 14 per cent, or that of the material used as a basis of comparison, whereas that of a similar group of pituitaries from males of the same age was only 6 per cent and that of another group of pituitaries from males of 1 to 2 years was only 5 per cent. The data from this age to that of 20 years and again from the ages of 25 to 35 are unfortunately very scanty, but they indicate a gradual increase in the content of gonadotropic hormone in the pituitary, the amount being greater in women than in men. Up to the age of 30 years in both sexes with two exceptions the amount of gonadotropic hormone in the pituitary does not exceed 50 per cent or that in the standard material. One of the two exceptions a pituitary with an activity of 75 per cent was from a woman aged 22 years from whom no menstrual history could be obtained. The second a pituitary with an activity of 85 per cent was from a woman aged 44 years in whom menstruation had ceased about one year previously.

With the appearance of the menopause there is an abrupt increase in the gonadotropic activity of the female pituitary which persists throughout the remainder of life. All the pituitaries examined from women past the menopause showed a gonadotropic activity between 80 per cent and 354 per cent that of the standard, with the exception of a pituitary with an activity of only 38 per cent from a woman 53 years of age. There is therefore, after puberty an inverse relation between sexual activity, as indicated by the occurrence of menstruation, and the amount of gonadotropic hormone in the pituitary.

There does not seem to be the same rapid increase in the amount of gonadotropic hormone in the pituitary of the male after 50 years of age. The gradual increase that was observed up to 50 years is maintained, but not until an age of about 70 is there any evidence of a sharp rise in the content of gonadotropic hormone. Of the six pituitaries from men of 70 years of age or more that were examined, only two, at ages of 71 and 72 years respectively, showed a gonadotropic value greater than that of the standard preparation. One pituitary from a man of 89 years gave a value only 48 per cent of that of the standard.

#### Gonadotropic Activity of the Human Pituitary under Conditions of Increased Intracranial Pressure

The gonadotropic activity of the pituitary associated with normal and with increased intracranial pressure is shown in Figs 2 and 3, for the women and men respectively.

FIG. 2—The gonadotropic activity of the pituitary of women with normal and with increased intracranial pressure.

tively. Increased intracranial pressure, in either sex, does not appear to alter the amount of gonadotropic hormone in the pituitary although in both men and women with

high intracranial pressure the hormone content of the gland seems to be more variable than normally at the ages of 30 to 45 years. Since this variation might be due to loss of sexual function a comparison was made

FIG. 3—The gonadotropic activity of the pituitary of men with normal and with increased intracranial pressure.

between the degree of activity of the pituitary of women and the occurrence of menstrual dysfunction, and it seems that in some cases of increased pressure there is a premature rise in gonadotropic activity, similar to that which occurs shortly after the menopause (Fig. 2). There is, however, no regular correlation of this nature.

The degree of activity of the pituitary was also considered in relation to the duration of the increased intracranial pressure. When the sella turcica is normal in size it is probable that the increased pressure is due to a rapidly growing tumour and has been of short duration, whereas an enlarged and atrophic sella the floor of which is partly or completely absorbed is indicative of chronic high pressure from a slowly growing tumour.

In Fig. 3 is shown the effect of increased intracranial pressure of long duration (up to six years) on the gonadotropic activity of the pituitary of men. In such cases it is seen that the activity of the gland is normal, except in one case with an unusually high and in another with an unusually low hormone content.

#### Discussion

From the results given above it is seen that in man a relationship occurs between the content of the gonadotropic hormone in the anterior pituitary gland and the functional activity of the reproductive organs. In both sexes, from birth to the decline of sexual function, there is a gradual increase in the hormone content of the gland. At the menopause, however, there is a great increase in the amount of gonadotropic hormone in the pituitary of women, but in men this increase does not occur before senility, when it is probably associated with the decline of testicular activity. The significance of this increase in the amount of hormone in the pituitary as gonadal activity declines is difficult to explain. It seems certain that lack of gonadotropic hormone is not the cause of the loss of ovarian and testicular function.

likely the decline of sexual function may be attributed to the gonads becoming insensitive to stimulation and the greater hormone content of the pituitary at this time may be due to increased secretion by the gland in response to the insensitivity of the gonad. It is unlikely that the increased activity of the pituitary is due to accumulation of the hormone in the gland through its failure to be released into the circulation since after the menopause a gonadotropic hormone which is probably of pituitary origin can be extracted in appreciable quantities from the female urine. Possibly the increased amount of hormone in the pituitary and in the urine after the menopause is due simply to the failure of the gonad to utilize existing supplies.

Since there is a great increase in the activity of the pituitary after the natural decline of reproductive function it might be expected that it would occur if the normal activity of the reproductive organs is otherwise impaired. Such impairment is sometimes seen in cases of cerebral tumour with an increased intracranial pressure which may disturb or even suppress the menstrual rhythm. The results obtained on the pituitaries of such patients were rather inconclusive although the activity of some of the glands tended to be greater than normal. It is not known whether this is due primarily to a disturbance of ovarian function or to the direct effect of the increased pressure on the pituitary. The amenorrhoea in all the cases was of short duration so that no comparison could be made between the duration of menstrual dysfunction and the activity of the pituitary.

From the action of human pituitary tissue on the ovary of the normal immature rat it cannot be decided whether there is a change at any stage of life in the qualitative nature of the gonadotropic complex of the human pituitary. It is hoped that experiments at present being made in conjunction with Dr R. L. Noble on hypophysectomized rats will throw light on this question.

The experiments of Saxton and Loeb (1937) in which human anterior pituitary tissue was implanted into immature guinea pigs suggested that during childhood the pituitary contains follicle stimulating hormone and only small amounts of luteinizing hormone but that later in life there is an increase in the amount of the latter substance in the pituitary of individuals of either sex during or after the period of sexual activity. It is possible that the discrepancy between these observations and those recorded above may be explained by reference to the different test animals used.

#### Summary

After being desiccated in acetone 109 human pituitary glands were assayed individually on groups of immature rats for gonadotropic activity. Fifty-two of the glands were from patients with increased intracranial pressure due to cerebral tumours while the remaining fifty-seven glands from cases with normal intracranial pressure served as controls. The activity of each gland was expressed as a percentage of that of a mixed sample of human pituitaries which was used as a standard preparation.

The control series showed that the gonadotropic activity of the pituitary varies with age. During early childhood the amount of hormone in the gland is small but it increases slowly to the end of the period of sexual activity. In women at the menopause there is a sudden rise in the activity of the pituitary but in men a corresponding increase does not occur until about the seventieth year. The significance of this is briefly discussed.

The amount of gonadotropic hormone in the pituitary of patients with increased intracranial pressure tends to be more variable than in normal subjects. Several of the women showed menstrual dysfunction and there was a suggestion of a premature rise in the amount of gonadotropic hormone in their pituitaries. There appears however to be no relation between gonadotropic activity and the duration of the increased pressure.

We desire to thank Dr J. E. Greenfield of the National Hospital Dr A. C. Crooke of the London Hospital Dr W. G. Barrard of the L.C.C. and Dr G. H. News of the Sick Children's Hospital for assistance in the collection of the pituitary glands used in this work.

## THE BIOLOGICAL NATURE AND QUANTITATIVE VARIATION OF THE GONADOTROPIC ACTIVITY OF PREGNANT WOMEN'S SERUM

BY

M. BOYCOTT, M.B., B.S., B.Sc.,\*  
*Obstetric Unit, University College Hospital, London*

AND

I. W. ROWLANDS, Ph.D.  
*National Institute for Medical Research, London*

It is already known that gonadotropic material extracted from pituitary tissue differs in its biological reactions from that of human urine of pregnancy. When tested in immature rats pituitary extracts cause an almost unlimited increase in ovary weight whereas urinary extracts in which the gonadotropic material is probably of placental origin cause only a strictly limited response. Also in hypophysectomized immature rats pituitary extracts will produce follicular growth and luteinization leading to increase in ovary weight. Urinary extracts in similar animals give little if any increase in ovary weight although considerable luteinization takes place. These and other experiments suggest the existence of two gonadotropic factors—that is, follicle stimulating hormone and luteinizing hormone only the latter being present in extracts of urine of pregnancy.

The investigation described below was made to ascertain some of the biological properties of the gonadotropic material which can be extracted from human blood serum during pregnancy and to compare it with gonadotropic material from other sources particularly with highly purified extracts from pregnant mare serum.

Quantitative estimations of the amount of gonadotropic substance present in the blood of pregnant women have been made by Evans, Kohls and Wonder (1937) who found that its concentration was at a maximum between the thirtieth and the forty-sixth day (pregnancy being dated from the beginning of the first missed menstrual period) at the same time as the gonadotropic substance in the urine reached its maximum. On the other hand Kennedy (1933) found in a very wide range of cases that as pregnancy advances there is a gradual increase in the concentration of the substance in the blood. The present work shows that there is a high peak in the concentration

\* B.D.H. Research Fellow since October 1937.

of this substance in the blood serum during the tenth to sixteenth weeks of pregnancy. No gonadotropic substance could be detected in the blood of non-pregnant women by the method adopted, although Frank and Salmon (1935) claim to have found small amounts, and to have been able to detect a regular alteration of its concentration during the menstrual cycle.

### Methods

Samples of about 20 c cm of blood were taken from the median basilic vein and allowed to clot in a sterile test-tube. The clot was later compressed, and the serum decanted and centrifuged. A large number of such

was calculated, the data being given in Table I and in Fig 2.

In all cases the period of pregnancy is calculated in weeks from the date of the first day of the last menstrual period, so that in Fig 2 a deduction of about two weeks should be made to obtain the probable time after fertilization.

### Results

#### COMPARISON OF THE GONADOTROPIC ACTIVITY OF PREGNANT WOMEN'S SERUM WITH THAT OF OTHER EXTRACTS

The type of response given by the gonadotropic substance present in human pregnancy serum is compared with that given by a human pituitary extract and that of a human urine of pregnancy extract in Fig 1. The dose-response curve of the last mentioned substance is taken from the results of Deanesly (1935), and that of the human pituitary extract from the results of Henderson and Rowlands given on page 1094 of this issue.

The constantly rising curve representing the activity of the human pituitary extract shows that an unrestricted response can be obtained in the rat as judged by the weight increase in the ovary. On the other hand, urine of pregnancy extracts give a response which reaches a constant maximum of 40 mg. The response given by the pregnancy serum extract (PWS 77) is similar in character to that of the urinary extract. Using the same method of assay, however, it is seen that a slightly greater response is obtained with the pregnancy serum extract than with the urinary extract. Since Saxton and Loeb (1937) found that the human pituitary during pregnancy contains no measurable amount of gonadotropic hormone, it is likely that the gland is secreting this hormone into the circulation as rapidly as it is produced, and that its

FIG 1—Comparative activity of gonadotropic extracts from human pituitary, pregnancy urine and pregnancy serum on the weight of the ovary of the immature rat.

samples, taken at random at different stages of pregnancy, were pooled (total volume = 710 c cm serum), and an extract (PWS 77) weighing 614 mg was prepared by the method described by Freed (1936). This substance was used for the construction of the dose-response curve shown in Fig 1.

Assay of this extract was carried out by injecting groups of ten to twenty immature female rats weighing 40 to 50 grammes once daily for five days. They were killed twenty-four hours after the last injection, the ovaries and uterus were dissected fixed in Bouin's fluid, and the following day transferred to 70 per cent alcohol and weighed on a torsion balance. A large number of individual samples of untreated serum were then assayed in the same way on groups of five rats. An amount of serum was injected which was expected to produce ovaries weighing between 14 and 30 mg, the weight of the normal rat ovaries at this age being about 10 mg. It was found that the volume of serum required to produce a response within these limits varied from 0.025 c cm to 1 c cm, depending on the period of pregnancy. All samples were injected in a volume of 0.2 c cm daily, when a smaller amount of serum had to be injected it was diluted to this volume with saline. The amount of the standard extract, converted into an equivalent volume of original serum, required to produce the same response as that obtained with each sample of serum was calculated, and the activity of each sample was then expressed as a percentage of that of the standard extract. The mean monthly percentage

presence in the blood probably accounts for the slightly greater response obtained with the serum extract than with the urinary extract.

Further evidence of the nature of this substance in the blood during pregnancy is obtained by its effect on the hypophysectomized rat. Only a few preliminary experiments have been done, but the injection of 2.5 mg of the extract PWS 77 into rats at two days, eight days, and twelve weeks after hypophysectomy failed to produce vaginal opening or to increase the weight of the ovary. Histologically, the ovaries show no follicular development, but some increase in the stromal tissue. These observations are therefore in agreement with those in which gonadotropic extracts of pregnancy urine are used.

The only other species which is known to contain a gonadotropic substance in the blood serum during pregnancy is the mare. Highly purified extracts of this substance are now available, and, tested on the immature rat, they give an unlimited response in the ovary similar to that evoked by horse or human pituitary (Rowland, 1938). With this substance ovaries averaging over 200 mg have been obtained. These extracts also produce follicular growth and luteinization in the ovary of the hypophysectomized rat.

There is thus a qualitative difference between extracts of pregnant women's serum (mainly luteinizing hormone) and pregnant mare's serum (follicle stimulating and luteinizing hormones) which can be shown from assays on immature and hypophysectomized rats.

# QUANTITATIVE ESTIMATIONS OF GONADOTROPIC ACTIVITY OF HUMAN SERUM DURING PREGNANCY

The mean monthly value of the activity of a number of samples of human pregnancy serum is given in Table I and Fig. 2 the value being expressed in terms of the activity of the preparation PWS 77. A number of samples of serum from non pregnant women were pooled and in an amount of 2.5 ccm per rat produced no effect on the

TABLE I—Percentage Activity of Samples of Human Pregnancy Serum in Comparison with Extract of PWS 77. The Samples are Grouped at Monthly Intervals

Mean Duration of Pregnancy (Weeks)	Number of Samples Tested	Percentage Activity in Relation to that of Extract of PWS 77 (a)
6.5	3	67
7	3	261
11.5	12	222
17	27	53
20	15	34
24.5	13	16
29.5	5	50
32.5	8	35
33	8	51

FIG. 2—Graphical representation of data given in Table I

ovary. Only very few samples taken during the early weeks of pregnancy were available but it is clearly shown that by the sixth week the gonadotropic substance is present and very shortly afterwards increases rapidly in its concentration. The maximum concentration of gonadotropic activity in the serum is found over a short period between the eighth and twelfth weeks pregnancy being dated from the first day of the last menstrual period. Subsequently there is a somewhat less rapid decrease in concentration the low level which is found in late pregnancy being established at about the twentieth week. From this time to the end of pregnancy the mean activity of the samples was shown to be about 40 per cent of that of the extract with which it was compared.

The very wide scatter of the points (from which the curve in Fig. 2 was constructed) during the eighth to the fourteenth week (30 per cent to 640 per cent) suggests that the maximum concentration of the gonadotropic substance in any particular pregnancy is either transitory or very variable. By making repeated estimations in the blood and urine of a few cases throughout pregnancy Evans Kohls and Wonder (1937) and Browne and Venning (1936) who made similar urine estimations found that in each instance the concentration of this substance was at a maximum for only a very short period and both these groups of workers give figures which show that the maxima vary greatly.

## Discussion

The significance of the presence of the gonadotropic (mainly luteinizing) substance in the blood and urine during pregnancy with a sharp rise and an equally rapid decline in its concentration during the second to fourth months is not understood. Browne and Venning (1936) who offered an explanation for its occurrence point out the importance of the placenta in man in superseding the ovary during this period of pregnancy as the seat of production of the corpus luteum hormone (progesterone). The placenta secretes large amounts of the gonadotropic luteinizing hormone which maintains the function of the corpus luteum at a certain concentration of which is necessary in the blood. On the regression of the corpus luteum the placenta itself produces progesterone and Browne and Venning suggest that the concentration of the gonadotropic hormone falls in the blood being now required only in the placenta where both this hormone and the luteal hormone are then forwarded produced.

This however does not satisfactorily explain the very abrupt rise and fall in its concentration during the critical time of the regression of the corpus luteum and the assumption of the luteal function by the placenta. It does not appear likely that this is a coincidence. Rather it seems that the great increase in production of gonadotropic substance serves to prolong the life of the corpus luteum as long as possible during this transition period and to stimulate the placenta to assume its new function. It is recognized that failure of the placenta to produce progesterone at this period leads to abortion. A clue to the significance of the rise in the secretion of gonadotropic hormone during the second to fourth months of pregnancy may be forthcoming from the observation of Browne and Venning that the characteristic rise in the excretion of this hormone is not so great in cases of habitual abortion. If this is generally so then favourable results might be obtained by the injection of urine of pregnancy extracts at this stage in such cases. Good results have been reported from the use of progesterone in cases of threatened abortion but the stimulation of the luteal cells of the placenta to secrete progesterone by the injection of extracts of gonadotropic hormone would appear to be a more rational method of correcting the physiological defect.

## Summary

A large number of samples of serum were obtained from pregnant women and assayed for gonadotropic activity, a bulk preparation from pooled samples being used as a standard of comparison and for determining the general gonadotropic properties. It is shown in contrast to pregnant mare serum extract that extracts of human pregnancy serum behave similarly to extracts of urine of pregnancy in that (a) they cause only a limited response in the rat ovary judged by increase in ovarian weight and (b) they produce no follicular growth in the ovary of the hypophysectomized rat.

Assays on the individual samples of serum taken at different stages of pregnancy show that the concentration of gonadotropic substance rises rapidly from the sixth week is at a maximum from the eighth to the twelfth week and thereafter declines to a low level which is fairly constant from the twentieth week to the end of pregnancy. By the technique of assay employed no gonadotropic activity could be detected in the serum of non pregnant women.

The significance of the presence of the gonadotropic substance is discussed in relation to the luteal activity of the placenta

We wish to thank Dr R K Callow, who prepared the extract (PWS 77) of pregnant women's serum

## TREATMENT OF CHANCROID WITH SULPHANILAMIDE

BY

R. C. L. BATCHELOR, M B, F R C S Ed, D P H.

AND

ROBERT LEES, M B, F R C P Ed

(From the Department for Venereal Diseases, Royal Infirmary, Edinburgh)

Chancroid is an ulcerative condition of the genitals due to infection with Ducrey's bacillus, and is observed more frequently in males than in females. The genital ulceration is often followed by the formation of large inguinal buboes. A provisional diagnosis may be made on clinical grounds, since the ulcers have a characteristic appearance, but in addition there is a specific test—Reenstierna's test. In this test 0.2 c cm of Dmelcos testing vaccine (1 c cm = 450 million organisms) is injected intracutaneously in the forearm. After forty-eight hours there is a marked local reaction around the injection, with a papule and often a pustule or a necrotic area. It is necessary to exclude syphilis in every case, and this is done by dark-ground examination of the exudate from the ulcers on three successive occasions at intervals of twenty-four hours. During this period saline soaks are applied to the ulcers. The blood is examined at regular intervals by the Wassermann and Kahn tests.

The usual treatment is by securing free drainage of the ulcers, applications of weak antiseptics such as eusol, etc., and intravenous injections of a vaccine of Ducrey's bacillus—Dmelcos vaccine. Injections are given on alternate days or as determined by the general reaction of the patient. The initial dose is 0.5 c cm (120 million organisms) and each successive dose is increased by 0.5 c cm. The general reaction is usually severe: a temperature of 103° F frequently follows in about eight hours and returns to normal in twelve hours. This treatment is not suitable for ambulatory patients, and patients are usually in hospital for at least two weeks.

### Sulphanilamide Treatment

Following a suggestion of Dr McGregor Robertson of Glasgow, made at a meeting of the Scottish Division of the Medical Society for the Study of Venereal Diseases, we have treated ten cases of chancroid with sulphanilamide by mouth. Four cases had relapsed after treatment with Dmelcos vaccine.

**Case 1**—A man was admitted to the Royal Infirmary Edinburgh with genital ulceration and an inguinal bubo. Reenstierna's test was positive. There was no evidence of

syphilis. Treatment with five injections of Dmelcos vaccine was followed by the rapid disappearance of the sores and the bubo, and the patient left the ward. Ten days later he reported to the outpatient department with a large bubo. Treatment with sulphanilamide by mouth was given, and the bubo healed in six days. This patient has been under observation for thirty days since treatment was stopped; his condition remains normal.

**Case 10**—A woman had previously been treated for syphilis and gonorrhoea, treatment being discontinued before clinical or bacteriological cure. She was referred back to the clinic by the prison medical officer on account of genital ulceration of ten days' and left inguinal bubo of five days' duration. The introitus vaginae was surrounded by shallow ulcers, ragged and with undermined edges. The bubo was about three inches in diameter. It was slightly tender, but no softening was detected. The serum from the ulcers did not contain *Sp. pallida* and Reenstierna's test was positive. The blood Wassermann and Kahn tests were also positive. The patient was given sulphanilamide by mouth—6 grammes a day for three days, then 4 grammes a day for four days. Healing was rapid and complete. On the sixth day the ulcers had healed and the bubo was almost completely absorbed. On the tenth day the patient's condition was restored to normal.

Table showing Summary of Cases

Case No	Ref No	Sex and Age	Genital Ulcer	Bubo	Total Dose of Sulphanil	No of Days Treatment Required	Previous Treatment
1	C9877	M 34	+	+2	Grammes 57	11	5 injections Dmelcos 10
2	C9928	M 55	+	+2	53	10	5 injections Dmelcos 10
3	D48	M 29	+	+2	46	8	4 injections Dmelcos 10
4	C9788	M 42	+	+1	36	10	5 injections Dmelcos 10
5	B	M 31	+	+2	68	5	Nd
6	D164	M, 23	+	+1	40	7	Nd
7	D1800	M 27	+	-	52	8	-
8	D3489	M 21	+	+2	76	10	-
9	D3497	M 18	+	-	36	11	Syphilis
10	D216	F 25	+	+1	34	7	Syphilis & Gonorrhoea

Average dose of sulphanilamide 50 grammes  
 treatment required 9 average number of days

### System of Treatment and Observation at Present Adopted

First, second, and third days. Dark ground examination of serum from ulcers, saline dressings applied to ulcers. Reenstierna's test carried out, Wassermann and Kahn tests of blood.

	Male	Female
4th and 5th Days Sulphanilamide	8 grammes a day	6 grammes a day
6th 7th 8th and 9th Days Sulphanilamide	6 grammes a day	4 grammes a day

The use of sulphanilamide is not devoid of risk. Case 5 was that of a man, aged 31, whose co-operation in treatment was not perfect, as he had eaten three aspirin tablets during five days' treatment and had taken two aspirin tablets during five days' treatment. After 34 grammes of sulphanilamide had been taken in five days he became sick and vomited. On this he had felt weak. On examination he showed a striking degree of pallor. The pulse rate was 120 per minute and the temperature 102.2° F. On the next day he could not sit up in bed to take food, and had to be fed—even the exertion of speaking tired him. The chancroid, however, healed rapidly, with rapid subsidence of the adenitis without abscess formation.

It was observed in one case that evidence of syphilis is not derived by this treatment in Case 9 dark ground examination of the sore was negative. The ulcers healed rapidly under sulphamamide treatment but there was evidence of generalized syphilis and positive Wassermann and Kahn tests three weeks later.

Case 5 was treated initially by injections of solu-septisine and the clinical response appeared satisfactory.

### Summary and Conclusions

- 1 Ten cases of chancroid have been treated by sulphamamide. A rapid cure was effected in all.
- 2 Sulphamamide does not interfere with Reinstierna's test.
- 3 Four of the above cases had relapsed after treatment by Dmeleos vaccine intravenously.
- 4 The good results of treatment appear to be permanent.
- 5 This method of treatment is suitable for ambulatory patients and out patients but strict supervision is required when large doses are given.

## Clinical Memoranda

### A Case of B coli Meningitis

This condition is apparently a well recognized though uncommon cause of neonatal death. Craig (1936) gives a full account of twenty one cases of neonatal meningitis of which ten were due to *B coli* alone. Cruickshank (1930) found meningitis in 4 per cent of 800 neonatal necropsies. The following are some details of the case which I saw.

#### CASE REPORT

Mrs. A gave birth to a healthy child of 11 lb. on December 20 1937. It was her second baby. The confinement was quite straightforward and both did well. I paid my last visit on December 30 leaving a competent district nurse in charge. Late on January 2 1938 I was called to see the child as it had refused all feeds that day appeared unusually quiet and occasionally cried in a peculiar way. It had been perfectly normal the previous day. I found the baby looking very ill with a temperature of 100.5 F a pulse rate of 150 and a respiration rate of 38. There were no physical signs except a patch of stomatitis in the left cheek. The fontanelle was not tense or distended there was no cervical rigidity and the ears were normal. The infant showed no interest or resentment on examination and refused the breast. There was a vague history of mild convulsions that day. In spite of taking some expressed feeds and water it died early the following morning. At the necropsy the cerebrum was extensively covered with a thick purulent exudate from which was grown a pure culture of non-haemolytic *B coli*. There were patches of stomatitis in the mouth which I regret I did not have cultured.

#### COMMENTARY

The striking points were the brief history the absence of indicative physical signs and the gross pathology found post mortem. In his series Craig observed prematurity and feebleness at birth in 70 per cent and lesions of skin or mucous membranes in all but three. Here there was definite stomatitis as in three of his cases. Other accompanying conditions quoted were otitis pneumonia colitis

and cellulitis of the scalp. He observed that the main clinical characteristics were lack of desire for fluids increasing bodily weakness and loss of or failure to gain weight. Fever was never high reflex changes were in constant conditions were fairly frequent convulsions were present in only 10 per cent and anuria was common in terminal stages. The average age at death was 10.8 days. Gibbins (1932) suggests that the adaptability of the infantile skull explains the soft or spongy fontanelle and probably the absence of early signs of increased intracranial tension hence the difficulty of early diagnosis. Von Reuss *et al* (1935) give the late appearance or absence of convulsions as a strong diagnostic point against intracranial haemorrhage. With sepsis of mouth or ears it may be caused by local spread but actually it is probably a septicaemia due according to Cooke and Bell (1922) to the increased permeability of the intestinal mucosa in infants with an absence in the blood of normal agglutinins for *B coli*. Though Neff (1924) reports a recovery there is no reference to treatment in the literature.

My thanks are due to Dr. Robo of Exeter for his pathological reports.

### Vulvo-vaginal Diphtheria

Cases of vulvo-vaginal diphtheria are rare enough to merit a note when they occur. The following case had some interesting features.

#### CASE REPORT

A B. a girl of 8 years suffered from a "cold in the head" on January 18 1938. On January 23 her sister aged 2 years developed a sore throat and was removed to hospital on the 25th suffering from severe faucial diphtheria. On the 27th a brother aged 3 years was removed to hospital also suffering from faucial diphtheria. Contact-swabbing of the members of this family on January 26 showed that the girl A. B. and a brother were both throat carriers. They were excluded from school and were directed to attend the school clinic for supervision. On January 25 the child A. B. began to complain of slight urinary disturbance which gradually got worse and on February 3 Dr. Dingle was called. He suspected vulval diphtheria and took a swab which subsequently yielded diphtheria bacilli in pure culture. The child was therefore removed to Sheriff Hill Isolation Hospital on February 4.

On admission the patient who was well nourished presented some excoriations of the nares accompanied by a slight discharge from the nose. There was nothing abnormal about the throat or neck glands. The vulva showed definite inflammatory changes. The skin of the perineum had several excoriated papules while there was a profuse and offensive watery discharge from the vagina. On inspection it was seen that the vaginal mucosa visible through an annular hymen was covered with white membrane. Upon the inner surfaces of the labia minora opposite the vaginal introitus there were two small shreds of membrane one on either side. The child was at once given 60 000 units of diphtheria antitoxin and swabs were taken from the vulva throat and nose while a direct smear was made of the vaginal discharge and

examined for gonococci with negative results. The throat swab was negative, but the vulval and nasal swabs were afterwards reported positive and on being submitted to a virulence test at the Bacteriological Laboratory of King's College Newcastle, were found to show virulent organisms of the 'gravis' type in each case.

The girl showed slight pyrexia for two days, while the urine was albuminous for a week. On February 7 the excoriation was healing the discharge had markedly diminished, while the membrane had disappeared from the labia and was only visible to a slight extent on the anterior wall of the vagina. By February 9 the improvement had continued but a little membrane was still evident on the right side of the vagina fairly high up. Subsequent progress was not abnormal, and on February 22 swabs were negative for diphtheria bacilli. It was noted during convalescence that the child tended to the habit of masturbation. She was allowed up on February 24 and was discharged on March 8 in perfect health.

#### COMMENTARY

I have already reported (*Journal* 1934, 1, 1074) a case of vulvo-vaginal diphtheria which was admitted to a venereal diseases ward. Then, as in the present instance, associated cases of clinical diphtheria were noted. It would seem that in the present case the child developed a diphtheritic infection of the nose which was missed, but which infected two other members of the household with faucial diphtheria, and spread in the patient herself, through her habits, to the vulva.

Gateshead

### Acute Perforative Appendicitis

The following record of a case of acute perforative appendicitis in a child of two months may be of interest.

W.W. aged 2 months was admitted to hospital on March 2, 1938 with a history of screaming with pain, persistent vomiting and constipation of twenty-four hours duration. The temperature was 102.6, the pulse 160, and respirations 60. On examination the patient was a very ill, poorly nourished infant with sunken fontanelles and drawn dehydrated appearance. Nothing abnormal was found in the chest. There was a large hard tender swelling in the right inguinal region extending into the scrotum. This had been present since birth but had become larger during the past twenty-four hours. No impulse was observed on crying. The mass was irreducible, but there was no abdominal distension. A small enema produced a copious constipated result. Vomiting ceased and feeds were well taken. The temperature fell to 100 and for thirty-six hours the child improved steadily.

At 7.20 on the morning of March 27 I was called because the child had suddenly collapsed, was grey in colour and quite pulseless. He had vomited a little during the night. With warmth and oxygen the general condition improved, and at 2.30 p.m. under a local anaesthetic, a small incision was made over the external inguinal ring. A large hernial sac was dissected out and opened. The sac was completely filled with a normal caecum, but the appendix was perforated and adherent to the fundus of the sac. The appendix was resected, the stump carbolyzed, the caecum replaced, and the sac excised. A small rubber dam drain was left in for forty-eight hours. There was a slight discharge purulent for two days and serous for two days but the temperature came down to normal. The wound healed and recovery was uneventful. The patient was discharged on April 10 quite well and rapidly gaining weight.

## Reviews

### THE MEDICAL ANNUAL, 1938

*The Medical Annual: A Yearbook of Treatment and Practitioner's Index 1938*. Edited by H. Letheby Tidy, M.A., M.D. Oxon., F.R.C.P., and A. Rendle Short, M.D., B.S., B.Sc., F.R.C.S. (Pp. 696, 103 figures, 68 plates, 20s. net). London: Simpkin Marshall, Ltd. Bristol: John Wright and Sons, 1938.

This annual review of the progress of treatment, now in its fifty-sixth issue, has established itself as a guide to developments in medicine and surgery. Its general arrangement is well known. The matter is in alphabetical order under disease headings, and gives a summary of recent papers on these subjects. As always, the information is compact and sufficient. The editors introduce each year some interesting features, and in this volume special articles cover the diseases common to animals and man, blood groups, the disturbances at the menopause, and the present position of prontosil and the sulphonamides in relation to infective states. Professor Heathcote, in dealing with the last subject, states that while it is too early to be dogmatic it seems that the outlook for a patient with streptococcal infection has been materially improved by the use of the sulphonamides. Several of the newer chemotherapeutic agents for use in trypanosomiasis (trypan blue, trypan red, germanin) belong to the group of sulphonated dyes. It has now been possible to obtain and use several of the group of sulphonamides, introduced under various trade names. The results in puerperal septicaemia, erysipelas, scarlet fever, streptococcal meningitis (the drug is found to enter readily the cerebrospinal fluid and to be maintained there at a level slightly below that in the blood at the same time) showed its valuable properties in streptococcal infections and it has been used with advantage in gonorrhoea and coliform infections of the urinary tract. As always when used as widely as the prontosil group, toxic phenomena have been described: renal irritation, sulphemoglobinemia, a characteristic febrile reaction with or without the appearance of a rash, and in a few cases agranulocytosis has been reported as a sequel. Though too much should not be expected, the sulphonamide group of drugs has already made good in certain states.

Dr. Gardiner-Hill contributes a helpful discussion of the menopause and its disturbances, with suggestions as to their management. The menopausal syndrome is made up of disturbances of other endocrine glands as well as the ovary, of changes in psychological reaction, temperament, and emotions, and symptoms of irritability of the involuntary nervous system. Some of these are controllable by the physician. Professor Cameron's review of the diseases common to man and animals points out that in Great Britain most diseases of animals reach man either by personal contact with domestic animals or by contact with their products, such as milk, meat, hides. Milk is by far the most common means of infection, the most usual being tuberculosis, brucellosis or undulant fever, and diseases due to haemolytic streptococci. While some milk can only be produced under clean conditions by healthy cows, there is no doubt about the advantage of combining insulin with protamine, and the addition of zinc further stabilizes it. In this way the absorption of insulin is more gradual and the number of injections can be reduced even to one a day. Sir Walter Boddy and Brown discuss the application of the new insulin and

other matters of importance in the treatment of diabetes. The remaining contributions keep up the high standard expected in this valuable annual. It can be taken up and studied in in easy chair better than used as a work of reference since in the latter event it may be necessary to look through several recent volumes to obtain the information sought. In this regard we may question the advisability of removing the index from its customary position after the title page to a comparatively obscure place between miscellaneous information and advertisements. Surely continuity of form is wanted in such a handy and useful volume as the *Medical Annual*.

## X-RAY DIAGNOSIS

*A Textbook of X-ray Diagnosis* (In Three Volumes)  
Volume I By S. Cochrane Shanks, M.D., Peter Kerley, M.D., M.R.C.P., D.M.R.C. and E. W. Twining, M.R.C.S., L.R.C.P., D.M.R.C. (Pp. 591, 198 figures, 10s. net)  
London: H. K. Lewis and Co. 1938.

As diagnostic radiology is becoming more and more complex it is inevitable that specialists will arise in all its branches. The editors of this new textbook have wisely obtained the collaboration of radiologists and clinicians who are recognized as authorities in the various branches. A certain element of dogmatism results but this will prove of help to the post-graduate student who is particularly in need of authoritative textbooks. The first volume deals with the radiological examination of the cardiovascular system, the respiratory system and the urinary tract and male genital tract. The minimum of technical details is given and these are mainly concerned with the correct relationship of x-ray tube to patient in order to obviate distortion and with the preparation of the patient and the steps of the various surgical radiological procedures in cases of urological disease. The three editors of the textbook are each responsible for one system in this volume but perhaps it would have been well had the first volume covered the cardiovascular and respiratory systems and that section on the urinary system added to Volume II which covers the radiological examination of the abdominal viscera.

Dr Peter Kerley has dealt with the x-ray appearances of the heart and aorta in health and disease. The various methods of examination employed by the radiologist including kymography and x-ray cinematography are described and evaluated. Dr Twining is responsible for the section on the respiratory system. He is equally insistent on the value of radiography in diseases of the chest and on the need for the most careful consideration by the radiologist of the clinical aspects of the case and of the results of other investigations. Unfortunately the latter point of view is not universal among radiologists though in their defence it is agreed that too often is the radiologist provided with quite inadequate clinical data regarding the patients whom he is called upon to examine. The third section on the urinary tract and the male genital tract is in the capable hands of Mr Jennings Marshall and Dr Cochrane Shanks. Their subject is most completely dealt with and the collaboration of surgeon and radiologist ensures that the role of each procedure of investigation of urological cases is evaluated in a critical fashion.

Many textbooks on radiology suffer from indifferent illustrations and it is a pleasure therefore to emphasize the very high standard of those accompanying the text. The editors and publishers are to be congratulated on the production of a textbook which is likely to become the standard English work on the subject both for the post-graduate student in radiology and for the clinician.

## GENERAL THERAPEUTICS

*The 1937 Year Book of General Therapeutics* Edited by Bernard Fantus, M.S., M.D. and Samuel J. Nicholas, A.B., M.D. (Pp. 496, 38 figures, 2.50 dollars, 10s. 6d. net, Postage 6d.) Chicago: Year Book Publisher Inc. London: H. K. Lewis and Co. 1938.

Dr Fantus has once again produced an up to date summary of the development of therapeutics. The book is remarkably inclusive in scope and yet the process of epitomization has not been carried to such length as to make it difficult to understand rationale and technique of the various methods of treatment which are referred to. This is in fact the outstanding value of the book that having read any section the reader can then without difficulty proceed to carry out the particular form of therapy which interests him and will find that everything relevant to the technique, probable results and even complications has been set down clearly. With a work of this sort the great difficulty is always to decide what to discard and here again the editor may be congratulated on his choice which has eliminated with a few exceptions unimportant contributions to medical literature of the last year. On the other hand it can be stated without fear of contradiction that anyone wanting to find out what is the latest approved treatment for a particular disease will almost certainly find it set out in this work. It thus justifies itself and is a tribute to the industry of the editor.

## LECTURES ON RHEUMATIC DISEASE

*The Rheumatic Diseases. A Course of Lectures arranged by the Medical Staff of the St John Clinic and Institute of Physical Medicine* Edited by Sir Leonard Hill, M.B., LL.D., F.R.S. and Philip Ellman, M.D., M.R.C.P. With a Foreword by Sir Arthur MacNalty, K.C.B., M.D., F.R.C.P. (Pp. 270, 46 figures including 8 plates, 2 tables, 10s. 6d. net.) London: Edward Arnold and Co. 1938.

During the winter of 1936-7 a series of lectures was delivered at the St John Clinic and Institute of Physical Medicine, London. These have now been collected and published in the present volume under the editorship of Sir Leonard Hill and Dr Ellman. The course was started by Sir William Willcox with an aetiological survey of the rheumatic diseases. This is a general introduction with special reference to specific treatment by sera and vaccines. Dr Fortescue Fox in a discussion of the social and economic aspects points out the serious gaps in our knowledge, the efforts made in various countries to combat the effects of this group of diseases and the general scheme necessary to make a campaign against rheumatism successful. Dr Ellman takes up the various classifications which have been proposed and discusses the characteristics of the rheumatoid and osteoarthritic syndromes respectively. Dr Leonard Findlay gives an excellent survey of acute rheumatism in childhood and points out that the pessimism with which we are bound to regard established rheumatic carditis in children calls out for better housing conditions which have been shown to be effective in its prevention. Mr Timbrell Fisher in his lecture on the pathology of acute rheumatism and rheumatoid arthritis remarks that the streptococcus must be incriminated in each disease possibly with the addition of an allergic reaction or a virus or both. The relation of infections in the nose and throat and pelvis are discussed in the next three chapters and these are followed by a chapter on radiology in rheumatic disease from the diagnostic standpoint. Next come three clinical chapters

on muscular rheumatism, rheumatism of the spine, and sciatica and brachial neuralgia. A long chapter on the anti-streptolysins and blood uric acid in chronic rheumatic diseases is contributed by Drs Koerner and Poulton, and they find that 77.5 per cent of forty cases of rheumatoid arthritis are associated with the haemolytic streptococcus. Chapters on the physical and physiological basis of physical measures used in the treatment of rheumatic diseases are useful summaries both of the methods used and the rationale of their employment. Finally, treatment by light, hydrotherapy, drugs, and surgical and orthopaedic measures is discussed.

As will be seen, several interesting aspects of the rheumatic problem are dealt with in this book, and if the lectures do not cover the whole ground they will repay the reader as up to date expositions of the subjects under discussion.

### ELECTROCARDIOGRAPHY

*Essentials of Electrocardiography For the Student and Practitioner of Medicine* By Richard Ashman, Ph.D. and Edgar Hull, M.D. (Pp 212 100 figures 15s net) New York The Macmillan Company 1937

This work presents clearly the common abnormalities of the electrocardiogram, and explains briefly the principles on which the form of the curve, both physiological and pathological, depends. As clinically the disorders of rhythm are now ranked secondary in importance to the state of the myocardium, of which they are merely symptoms, the authors wisely deal last of all with the arrhythmias. Yet the latter occupy a relatively large part of the book, while the changes associated with cardiac infarction, now perhaps the most important single aspect of cardiography, are discussed rather too briefly. A short description of curves obtained with chest leads is included, but the technique employed does not happen to coincide with the one recommended for routine use by the Cardiac Society and the American Heart Association, the book being published a few months before this was made (see *British Medical Journal*, January 22, 1938, page 187). There are numerous illustrations, and their quality is uniformly good. The book will fully meet the requirements of the beginner, and may well be read by those more advanced in the subject.

### RADIOGRAPHY IN DIAGNOSIS OF LARYNGEAL TUMOURS

*Le Diagnostic Radiologique des Tumeurs Malignes du Pharynx et du Larynx. Étude anatomotopographique et Radiographique* By F. Baclesse. Preface by A. Hautant. (Pp 270, 236 figures, including several plates 100 fr.) Paris Masson et Cie 1937

Many attempts have been made to utilize radiography as an aid to the diagnosis of laryngeal disease. That it has not become more popular is due to the facility with which the larynx can be inspected either by indirect or by direct laryngoscopy, and the additional information to be obtained by the inspection of x-ray films has not been of great value. Among such attempts the work of Baclesse is exceptional, and he has shown how radiology may be employed as a subsidiary means in making a complete diagnosis of tumours in the larynx and pharynx. Inspection will reveal the presence and site of a tumour, the microscope will confirm its neoplastic nature and demonstrate its histological character, but even with this information it is often difficult or even impossible to estimate accurately the extent of a tumour, especially when it is no longer in an early stage and has become rather extensive. It is particularly difficult in such cases to determine the extent in the downward direction, where it

is least accessible to inspection. Baclesse shows in his book, which is so profusely illustrated that it is more an atlas than a monograph, how the extent of a tumour, especially its lower limit, may be defined by an x-ray film, and thus a complete diagnosis can be made. In addition certain tumours which cannot be seen on ordinary examination, such as subglottic tumours, may be revealed in an x-ray film.

The author gives a detailed classification of the tumours around the base of the tongue, in the lower pharynx and of intralaryngeal tumours. In his groups of x-ray films which are admirably reproduced on special paper he is able to show how the effects of treatment modify the appearance previously produced by the tumour. It is evident that special experience is necessary in the interpretation of such films, but Baclesse shows clearly that under favourable conditions this form of radiography can be made a valuable addition to the classical means of diagnosis. A careful study of the normal is naturally an essential preliminary, to which the author has devoted much attention.

### INSTITUTIONAL CATERING

*Scientific Catering for Institutions. A Handbook for Food Supervisors in Hospitals, Nursing Homes, Sanatoria, Hostels, Schools, Hotels, Boarding Houses, Etc.* By Juliet de Kay Whitised. With Appendices edited by Ethel Browning, M.D. (Pp 262 8s 6d) London Baillière, Tindall and Cox 1937

Large-scale catering seems at first sight to have little connexion with medicine, but it is clear that the food provided in hospitals may have a great deal to do with the success or failure of medical or surgical treatment. Miss Whitised is dietitian at Johannesburg General Hospital, and her experience is largely of South Africa. She is somewhat at a disadvantage, therefore, in writing for the English reader, for although feeding habits are similar here and in South Africa they differ in various respects. Further, the author tells us that no hospital in South Africa has an established dietetic department on the lines of those in the British hospitals, and the chapter on "How to Train as a Dietitian" would have been far better had it been edited by someone working in this country. About half the book consists of recipes and methods for large-scale cookery, grouped under various headings, and suggested menus for different types of people are given. This part of the book is good. A chapter entitled "The Model Kitchen" contains descriptions and plans of several large kitchens, including that for Harrods' staff. It would have been a much more logical arrangement to put this chapter immediately following the one called "Planning and Equipping the Kitchen" instead of ten chapters later. Dietaries in actual use in several institutions in South Africa and England are given and discussed, largely to the advantage of the former. In this respect the author's opinion appears to be somewhat biased. An entertaining description is given of the dietary of the competitors in the Olympic Games. The enormous quantities of meat eaten by the Americans and Germans are the most striking feature.

Miss Whitised may be an excellent caterer, but she is no expert on the scientific aspects of nutrition. The chapter on the dietary essentials and the foodstuffs in which they may be found should have been revised or alternatively omitted. Statements such as "Vitamins A and D in tomatoes, oranges, vegetables" can be passed over without comment. The book is of practical use to caterers in large institutions, but to the medical man it will probably not be more than theoretical interest.

## Notes on Books

Professor WILBERT C. DAVIDSON has carried out a very complete revision for a second edition of his synopsis entitled *The Complete Paediatrician* which struck a new line when first produced in 1934. New features of the second edition (Cambridge University Press 1935) include chapters on growth, development, nutrition and infant mortality. A vast amount of literature has been surveyed to bring the book up to date and as a ready work of reference it stands alone.

*The Management of the Sick Infant and Child* by Professor LANGLEY PORTER and Dr WILLIAM E. CARTER now appears in a fifth revised edition and its scope has been somewhat extended to an older group of patients so that the term "infants" no longer suffices for its title. Much new material has been included but none of the changes has altered the valuable practical nature of this useful book from the western side of the U.S.A. It is published by Henry Kimpton at 42s.

*Die Pathologische Anatomie des akuten Rheumatismus* by Professor H. CHIARI forms Volume V of *Der Rheumatismus* edited by Professor Rudolf Jürgens (Dresden and Leipzig: Theodor Steinkopff RM 6). The author discusses the general histological appearances characteristic of the tissue changes in acute rheumatism. They are brought about he says by processes which in their final stages show certain differences but are in essence uniform. He refers to Aschoff bodies, nodulous nodules and that particular alteration of the colloid connective tissue which Klinge called fibrinoid swelling. The second part of the book deals from the point of view of morbid anatomy with changes in single organs and systems produced by acute rheumatism: it should be read in the original by the interested student.

*Atmosphärisches Geschehen und witterungsbedingter Rheumatismus* by Dr EMIL FLACH forms Volume IV of the same series. The author found that colds occur at all degrees of wind strength and that the amount of cooling is without influence. Further the probability of catarrhal diseases declines with the increase of wind velocity. The tendency to fall ill is much less on very moist days than on dry ones.

*Children's Dreams: An Unexplored Land* by Dr C. W. KINNERS is a complementary volume to one published by the author shortly after the war but there is little really new in it. According to this somewhat superficial review of dream materials children's dreams fall in the majority of cases into one of three categories: simple wish fulfilments, fear dreams and kinaesthetic dreams. It is thought that a more intensive study of children's dreams would lay bare their inner urges and difficulties and so be of assistance in education and upbringing. The book is published by George Allen and Unwin at 4s. 6d.

*Über die Ernährung des Säuglings* by HANS BEUMER is now in a second edition published at Leipzig by Georg Thieme price RM 2. The author, director of the Paediatric Clinic at Göttingen in this little book on the feeding of the infant seeks to propagate a wider knowledge of the curdled milk among general practitioners. When the disadvantage of too great dilutions of milk for the artificially fed infant had been discovered soon after 1920 the author started feeding those infants with undiluted cow's milk with an addition of 2 per cent of flour and 3 to 6 per cent of sugar. Much better however is the use of curdled milk as recommended by Marriott in America. Such a milk may be produced by lactic acid or by other organic acids such as those contained in lemon or orange juice. There are powders for curdling milk and the author recommends especially the acitellen prepared according to his directions by the chemical factory Bockler Ludwigshafen.

## Preparations and Appliances

### MODIFIED SHIPWAY APPARATUS

Dr W. B. PRIMOSE (Glasgow) writes

The accompanying illustration shows a reconstruction of the Shipway apparatus I designed. In this a single rotating valve of simple pattern replaces the various rubber tube connections and non return valves at present in use the former of which are liable to wrong attachment. The valve at the same time gives any desired proportion of ether and chloroform with air or oxygen. Another position of the valve allows

both bottles to be filled thereby eliminating corks of doubtful fitting.

The supply and delivery tubes—the only tubes on the apparatus—are of thin flexible copper which permits of the vapours being heated to theatre temperature on their passage to the patient. This renders unnecessary the usual vacuum flask. This compact and fool proof unit with its accessories is carried in a neat attache case and is now manufactured by Anaesthetists Ltd 163 Hope Street Glasgow C2.

### MODIFIED LAURIE DRIP BULB

Mr J. LEIGH COLLIS (Birmingham United Hospital) writes

Considerable trouble is often met with when administering fluids intravenously owing to the ordinary type of drip bulb filling up. To deal with this the first improvement tried (Laurie) was to put one side tube at B. Then by closing the apparatus at A and opening B the fluid would run out into the vein while air was allowed to enter at B. However when the drip is running slowly it is difficult to get the fluid to run out into the vein. A second side tube was therefore made at C. Now by closing off the trans fusion fluid at A and opening B and C air is allowed to enter at B and the fluid runs out at C. The intravenous drip can then be restarted. Rubber bungs have been used at B and C. They are found to make the apparatus neater while at the same time being efficient. The drip bulb thus modified may be obtained from Messrs Salt and Son Ltd Birmingham 2.

## Nova et Vetera

### "A HUNDRED YEARS OF CHEMISTRY"

In his book with this title<sup>1</sup> Professor Alexander Findlay presents a serial view of the succession of events which make up the history of modern chemistry. Findlay has here characterized himself as possessed of the qualities needful for relating these events each in the right perspective, and the book he has produced is an entertaining and illuminative piece of history. The young chemist trained under modern teaching could have no appreciation of the efforts of the chemists of the past to clothe the facts they had found with theories which were satisfying, or of the many false foundations of theory laid on which nothing further was built, nor of the many times a true foundation was abandoned because it appeared, in the light of imperfect or incomplete knowledge, not to be tenable. There were it seems theories unheard of by the present generation, such as a formula for benzene, proposed by Ladenburg in 1869, which placed the atoms of carbon at the corners of a prism, and for a time the prism formula was a serious rival of the hexagon. The hypothesis of Avogadro was presented prematurely to men who were unable to grasp its implications or to free their minds from preconceived ideas.

Findlay begins everything at the beginning. The developments in chemistry due to the spectroscope started in 1758, when "the German chemist Andreas Sigismund Marggraf, a pioneer of analytical chemistry, had shown that the salts of sodium and of potassium can be distinguished by the yellow and the lavender colour which they respectively impart to a flame", and turning from the spectroscope to another subject he follows the train of events from the observation first made that certain colouring matters will dye wool but not cotton, to the later discovery that certain living tissues show a different absorptive power for different dyes—methylene-blue when injected into a living animal stains only the nerve tissues—and thence to the discovery of the selective absorptive power of organisms for materials having a specific toxicity for them, whence arose the treatment by which the spirochaete is destroyed by organic preparations of arsenic. Here the chemist and the physiologist meet and work on common ground.

Matters of such diverse kind as the disintegration of the atom and the nature of vitamins are included in the work and are discussed with an equal lucidity of treatment. The book can be read as freely for entertainment as for instruction and is a useful history of chemistry.

### SPONTANEOUS HUMAN COMBUSTION<sup>2</sup>

The issue of the *London Medical and Surgical Journal* of November 25, 1837, contains the following survey of recent cases of alleged spontaneous combustion of the human body in an unsigned article entitled "The Medical Jurist".

Dr Paris thinks that in these cases the body is never nearly consumed and that the combustion never originates spontaneously but there are many accounts of cases in which a very small portion only of the body is left and at Berlin an instance took place in which a flame, which issued from the fingers set fire to the surrounding substances. Blouquet has collected about twenty cases, and other authors have recorded many more. The Countess of Burdt who perished in this way was in the habit of rubbing her body with camphorated spirits. When discovered the head lay between the legs from which circumstance it was concluded that she was in a sitting posture when she died. A woman at Ipswich used to drink and smoke by the fire at night and was found one morning like a half-burned wooden log, a heap of cinders covered with a white ash. There was no fire in the

grave, a candle had burnt into the socket near the body. The case of the priest Bertholi is well known. He was found enveloped in a blue flame. Battaglini, the surgeon who attended him, found part of the arm consumed. Mortification ensued, he suffered under burning thirst, attended with vomiting, and succeeded by coma and died in four days. While the coma was present the body was so putrid that it exhaled an unportable odour. Worms crawled from the body while yet alive and the nails of the left hand separated. In most of the cases recorded the sufferers were addicted to intoxication, but not in all. They were either fat or very lean or very much debilitated though some exceptions to this state of things have occurred."

Little is heard nowadays on this macabre subject, which in the first half of the nineteenth century attracted much notice. We may recall that Charles Dickens makes spontaneous combustion the mode of death of alcoholic Mr Krook in Chapter XXXII of *Bleak House* and a lurid piece of writing it is. Dr W. A. Brend, in his *Handbook of Medical Jurisprudence* sums up the point of view of forensic medicine thus:

Spontaneous combustion of the body, in the sense that the layman attaches to the words never occurs, but very rarely a state of the tissues exists for which Dixon Mann suggests the term *preternatural combustibility*. The condition has been most frequently noticed in the bodies of fat bloated individuals who have been excessive drinkers. Probably, in such cases, inflammable gases are generated in the body after death and if a light is near, become ignited, leading to a partial consumption of the soft tissues."

### MORE OLD MEDICAL BOOKS

Hard upon the Sion College and Ham House library sales come two more containing old medical books of rarity and interest. The second part of the Ham House sale (Sotheby's June 20 and 21) has only a few—but they are really rare. First comes *Macer's Herbal* Practised by Doctor Lynacro. Translated out of laten into Englysshe, whiche shewing their Operacions and vertues, set in the margent of this Boke to the entent you myght knowe their Vertues. Imprinted by me Robert Wyer dwellynge in seynt Martyns Parvise at the seyne of seynt John Evangelyst besyde Charvinge Croc 1530. Only one other perfect copy is known that in the British Museum one imperfect copy is also known. The Lynacro mentioned is, of course, Thos. Linacre, 1460-1524 founder of the Royal College of Physicians, he was born at Canterbury, educated at Oxford and Padua and became a physician to both Henry VII and Henry VIII. Then there is a translation into English of Monardes's *News out of the New-Found Worlde* 1596, a rarer edition of which was in the Sion College sale. Next, Thomas Ryndal's *Compendious Declaration of the excellent vertues of a certain lately invented oile called for the worthiness thereof oile imperial* Venice Gryphus, 1551, of this apparently but two other copies exist. Another extremely rare production, in black letter, is *The Seeing of Urines*. "Here begynneth the seynge of Urine and of all the Colours that Urynes be, wth the medecines annexed to every Uryne, and every Uryne his Urinall medicine profitable for every man to knowe", London, Wm Poell 1562. Lastly, James Young's *Wounds of the Brain Proved Curable* 1682.

In the other sale (Hodgson's, May 26 and 27) there are to be noted a black-letter edition of Sir T. Ekot's *Casus et Health* 1580 (not, of course, an early edition of this classic), Bayfield's treatise *de Morborum Capitis* 1663, C. Gould's *The Royal College of Physicians of London and its Historical Account of Proceedings against Empiricks* 1684 (4 copies), a MS of the *Statuta Collegii Medicorum Londinensium*, P. Madan's *Essay of the Waters of Tanbridge* 1613 and M. J. S. *Essay on Mineral Waters of Castle C. Limerick*, Harvey's *De Febribus Tractatus* 1672, S. P. Sloane's *Account of a Medicine for Soreness and Distention of the Eyes*, Catherwood's *Method of Curing Apoplexy* 1715, J. Reynolds's *Prodigious Abstinence* 1715, *Twelve Months Fasting of Martha Taylor* 1669 and volumes of Sir G. Floyer's treatise on *The Pulse* 1707-10.

<sup>1</sup> *A Hundred Years of Chemistry*. By Professor Alexander Findlay. (Pp. 352. 15s. net.) London: Duckworth and Co., Ltd. 1927.

## WATER SUPPLIES AND RIVER POLLUTION

The tenth annual report of the Water Pollution Research Board has been issued by the Department of Scientific and Industrial Research (H.M. Stationery Office 9d). The Board carries out research mainly on the treatment of water for domestic supply and for other purposes, the treatment and disposal of sewage and trade effluents and on problems of river pollution.

### Water softening Materials

Experiments have been continued on the preparation of materials for softening water by the base exchange process. This process is used in household water softeners and is also employed on a large scale at a number of waterworks. The investigations of the Board have shown that satisfactory water softening materials can be prepared from fuller's earth which is found in parts of the British Isles. The base exchange capacity of the final product depends on the type of fuller's earth used, yellow weathered varieties being more satisfactory than blue varieties.

### Removal of Salts from Water by Resins

The discovery that acids, bases and salts can be removed from solution in water by means of synthetic resins has aroused widespread interest both in this country and abroad. It has been shown for example that fresh water can be prepared from saline water by treating it first with a suitably prepared base-exchanging resin and then with an acid exchanging resin. The removal of traces of deleterious substances from water used for domestic supply or other purposes is desirable in many parts of the world. For example, it is known that a defect of the teeth known as "mottled enamel" may be caused by drinking water containing as little as one part per million of fluorine in the form of compounds. Experiments are in progress to determine whether these compounds can be removed from water by treatment with suitable resins. Again in recent years considerable attention has been given by agricultural chemists to the presence of compounds of boron in water used for irrigation, certain plant diseases are caused by excessive or insufficient concentrations of the compounds. Recent work has shown that partial removal from water of boron compounds is effected by treatment with a resin prepared from a tannin.

### Lead in Drinking Water

Certain types of water take up appreciable quantities of lead from lead pipes and fittings. An investigation is in progress to determine the average quantities taken up by waters of different types under the conditions of household supply. A method is used in which a volume of 20 to 300 gallons of water is passed through a meter and then through a filter containing a mixture of chalk and magnesia which takes up the whole of the lead from the water, the amount of lead taken up is determined by analysis. Apparatus of this type has been tested in eight towns in England and Scotland. Average concentrations of lead ranging from less than 1 part per 10 millions to as much as half a part per million of water have been obtained.

### Milk Factory Effluents

Work on the purification of waste waters from dairies and milk products factories which is being carried out in collaboration with the milk industry has been continued. One of the most important results of the work has been to show that the loss of valuable products and by-products carried away with the waste waters from dairies and milk products factories can be considerably reduced by inexpensive modifications in the manufacturing processes. For example, when churns of milk are brought from farms to a central milk depot they are inverted and emptied into a large receiving tank. If sufficient time is not given to allow the churns to drain an appreciable quantity of milk remains in the churns and is later washed out and discharged with the waste waters. By a short increase in the time of drainage of the churns the

average quantity of milk carried away with the waste waters can be reduced from more than one half of 1 per cent to less than one quarter of 1 per cent of the milk handled. For a depot receiving 10,000 gallons of milk daily this represents a saving of over 9,000 gallons of saleable milk annually. Beside the saving of valuable material the polluting nature and thus the cost of treatment of the waste waters are greatly reduced. The work of the Board has shown that the unavoidable waste waters from dairies can be purified by processes similar to those used for the treatment of sewage.

Work in progress includes investigations on the biochemical and biological processes of purification of sewage by the activated sludge process, and on the removal of organic matter by flocculation and sedimentation.

## TUBERCULOSIS IN TANGANYIKA

The final report of Dr Charles Wilcocks on investigations carried out between 1930 and 1936 under the auspices of the Colonial Development Fund represents a sound piece of research, the conclusions from which add to knowledge on tuberculosis among primitive races. The results of 13,113 tuberculin tests showed that no part of Tanganyika Territory could be regarded as virgin soil. The lowest percentage of positive reactors in adult males was 4.6. The highest percentage in adults (males and females) was only 5 per cent less than that found in London by Dr Aron Hart. The result obtained showed however that the natives were more sensitive than Europeans to tuberculin and that strong reactions tended to occur in contacts. This confirms the findings already reported from South Africa. The tuberculin tests related to other findings showed that the tuberculin rates provide good indices not only of the amount of infection in the districts but also of the amount of actual disease. In Dr Wilcocks's opinion by far the most important factor in the epidemiology of native tuberculosis was contact with sputum positive cases. Apparently the great majority of the natives who have been infected are capable of resisting that infection though on the whole their resistance to tuberculosis is not so great as that of white races. In connexion with the allergic state of the natives a comparison is made between tuberculosis and malaria but Dr Wilcocks concludes that sensitivity and immunity seem to be more dissociated in tuberculosis than in malaria. The date of the first infection appears to be similar to that already described among South African natives.

Study of the incidence of tuberculous disease in the Tanganyika natives (both radiological and bacteriological examinations were carried out) showed that the large number of pulmonary cases were between the ages of 15 and 35 and that the curves in general bore more resemblance to those of the young adult type than those of the middle age type recognized in Britain. The incidence of disease in proportion to population was exceedingly difficult to estimate because it was impossible to examine large numbers or completely unselected natives. The figure of 11.55 per 1,000 of the population calculated over the whole of the places investigated is probably too high because it seems likely that more tuberculous patients presented themselves for examination than would be proportionate to the whole. Bovine tuberculosis is not considered at present to be a factor of importance. Finally it is of interest to note that examination of the x-ray films of the native cases of definite pulmonary tuberculosis showed a preponderance of acute galloping consumption and of bilateral disease. Fibrosis was not common being found chiefly in middle-aged people. The base of the lung was often affected. Cavitation was often seen but it was rare to see a zone of fibrous tissue around it. Dr Wilcocks concludes that on the whole the appearances while not so gross as would be seen in a virgin race were not so fibrous as are seen in civilized countries, these natives thus "lie midway between the completely primitive races and our relatively resistant selves."

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY MAY 21 1938

## MALNUTRITION IN AUSTRALIA

The Advisory Council on Nutrition, under the chairmanship of Dr J H L Cumpston, Director-General of Health, Australia, has recently issued a fourth report, which is of great interest. It reveals a relatively high incidence of malnutrition among children of school age, though, "generally speaking, the people of Australia are, by contrast with the older and more densely populated countries, well nourished and well developed." The surveys on which the report is based were made by Dr F W Clements with commendable thoroughness. In all, he examined 3,384 children in inland areas of Queensland, New South Wales, and Victoria. The methods of examination were of two types—physical and clinical. The physical method consisted of nine measurements so chosen as to enable the following standards of nutrition to be calculated: (a) height and weight for age, (b) weight for height, (c) arm-chest-hip index, and (d) "pelidisi" of Von Pirquet. The clinical method consisted of an examination of the eyes, nose, throat, and chest, together with a careful appraisal of the state of development and nutrition as assessed by general clinical observation and the application of Pirquet's "sacratama".\* By these two methods "it was possible to summarize the nutrition and to determine whether the state of nutritional development was 'satisfactory' or 'unsatisfactory'." Those children falling into the latter class, and a number of the 'satisfactory' type, were submitted to one or all of the following tests: (a) an x-ray examination of the epiphysis at the wrist, (b) an estimation of the haemoglobin, (c) Gothlin's capillary resistance test for scurvy and borderline scurvy, (d) a visual acuity test for partial night blindness.

"By the application of these methods it was possible to select the cases of malnourishment, and in the majority of these to detect the effects of the malnutrition." We would here remark that it is possible by these methods to detect *some* effects

of malnutrition—the range of possibility being limited by the limitations of the methods employed. For "malnutrition" is disorder of the function of nutrition from whatever cause arising, the chief cause being faulty food, and nutrition is the sum of the processes whereby structure and functions of organs or parts of the body are maintained. It follows, therefore, that only in so far as the methods of examination employed embrace all processes involved in nutrition can disturbance of nutrition (malnutrition) be fully detected. Nevertheless, the tests used by Dr Clements are more comprehensive than those generally employed, and in proportion to their comprehensiveness the value of the results obtained by them is enhanced. Evidence of unsatisfactory nutrition was found in 18.8 per cent of children in Western Queensland, in 23.7 per cent in New South Wales, and in 13.3 per cent in the north-western districts of Victoria. Previous surveys in inland South Australia had revealed unsatisfactory nutrition in 14 per cent of children, while reports received from Dr John Dale showed that among the pre-school children of Melbourne 21.7 per cent presented evidence of malnutrition. Dr Clements found no scurvy, probably because of the large potato diet and the antiscorbutic value of this vegetable. Rickets varied from 6 to 11 per cent and nutritional anaemia from 4 to 6 per cent of the children examined in different areas. Among children in Queensland whose nutrition was unsatisfactory, active rickets was found in 22.2 per cent and anaemia in 40 per cent. Both these conditions were attributed to mineral deficiency—the former to lack of calcium, the latter to lack of iron. Observations made on the teeth revealed such figures as 48.5 and 80 per cent of children in different areas having either carious or stopped teeth. Fluorine mottling of teeth was observed in two communities in Western Queensland. The condition occurs only in those children who have consumed from birth, or before the age of three, the local bore water containing 1.6 parts per million of fluorides.

In view of these and other findings the Commonwealth Advisory Committee again urges the necessity of increasing the consumption of protective foods, and emphasizes the value not only of whole milk but of skimmed milk and of goat's milk, meat and vegetables, potatoes, fish, and other sea food. It repeats the resolution recorded in the third report that "the provision of a daily supply of milk for school children distributed where, on inquiry, it was probably do the most good would be a measure of great public health value. Its ultimate effect in reducing the amount of hospitalization would probably be very great." It would be greater if combined with other foodstuffs so as to provide

\* *Sacratama* is Pirquet's word formula to indicate a child in a state of normal nutrition. The consonant *s* stands for *sanguis* (blood), *cr* for *crassitudo* (thickness or fat), *t* for *turgor* (water content), and *m* for *musculus* (musculature). The *a* after each of these letters represents the normal. By changing the vowels the intensity of any of the four qualities may be represented.

a diet containing all elements and complexes needed for normal nutrition. A tragedy of our times is that hospitals and other health services involving vast expenditure of public funds have to be maintained to remedy many ailments that need not arise were the knowledge of nutrition we already possess universally applied.

## RECENT EXPERIENCE IN TYPHOID FEVER

We publish to-day (p. 1085) a review by Sir William Willcox of the clinical features and treatment of typhoid fever based in part on experience gained among cases in the recent Croydon epidemic and a description (p. 1090) by Drs J. Fenton and C. P. Hay of circumstances in Kensington which led to the first recorded attempt at prevention of typhoid fever by means of serum. This attempt seems to have been successful although there is of course no actual proof that any of the individuals so treated had in fact been infected and the accompanying paper by A. Felix to whose work the production of this serum is entirely due records the antibody levels reached in the blood of those given the serum. As Sir William Willcox points out typhoid fever is a rare disease by comparison with forty years ago. An epidemic is as much an event as in other countries is an earthquake. It happens that there have been two epidemics on a large scale in England recently while several smaller outbreaks have occurred within the past few months including that at Hawick about which an authoritative statement has yet to be published. The wide publicity given to the danger of contaminated milk and water should lead to more general vigilance in these directions and the frequency of epidemics is almost certain to diminish. In these circumstances it may well be asked whether clinical material will be forthcoming for an adequate trial of new methods of treatment and prevention. Promising as the results with serum have been in both of these directions they are far from having reached the stage of unassailability from a statistical point of view. Another remedy which seems to merit more attention is sulphanilamide. This drug has a curative action in typhoid infection in mice comparable to that in streptococcal infection. Although Sir William Willcox's opinion that the drug is contra-indicated in typhoid fever must be received with respect it is right to require that this treatment be adequately tried unless this has already been done. Even if unavailing in the later stages it might well be effective earlier and the possibility of its exerting a protective action if given during the incubation period seems to have been entirely

overlooked. By analogy with experimental findings it is reasonable to hope that there would be such an action.

Although uncertainty about mode of employment and clinical effect is not to be wondered at in the case of new remedies it is perhaps a little disturbing and surprising that there should still be a difference of opinion on the advisability of giving vaccine during an epidemic. This question has been discussed several times in this *Journal* recently and conflicting views have been expressed. There are even elements of doubt in connexion with prophylactic vaccination generally, not of its efficacy which is unquestioned but of the best reagent to employ. On this and other matters connected with typhoid fever much useful information is to be found in an extensive monograph by W. Lewin<sup>1</sup> dealing with experiments on the Witwatersrand. Here again some promising though not fully conclusive results have been obtained with serum treatment and not only with a serum containing Vi antibody which is believed to be an essential element in the new serum now in use in England but with one dependent for its efficacy on O antibody alone. Lewin's most extensive and interesting studies are concerned with prophylactic vaccination which is employed on the Rand on a large scale. Three methods are used—ordinary bacterial vaccine and endotoxoid vaccine given by injection and a vaccine given by the mouth. This last highly debatable method of immunization advocated originally by Bezredka receives little support from the South African results. The evidence of preventive power is inconclusive and serological studies showed that contrary to several assertions by other authors antibody formation in consequence of this measure is negligible. It is very much to be hoped that studies now in progress at the London School of Hygiene will eventually place this whole matter on an assured footing. The isolation of the essential immunizing fraction from the typhoid bacillus and other bacteria is their object and there is good reason for hoping that such a product will eventually supersede the crude and variable reagents now employed for active immunization.

## POLIOMYELITIS IN VICTORIA

The current number of the *Health Bulletin* published twice yearly by the Department of Public Health State of Victoria Australia contains details of the 1937 epidemic of poliomyelitis in Victoria. This epidemic which started in Ormond a residential suburb of Melbourne and eventually spread over the whole metropolitan area of Melbourne as well as many parts

<sup>1</sup> Typhoid Fever on the Witwatersrand. *Publications S Afr Inst med Res* 1938 7: 413.

of the State, has differed in several respects from the previous epidemics which have occurred in Victoria and other parts of Australia. Poliomyelitis appears usually during the warm months, and in this country the late summer and early autumn is the time of its major incidence. In the Southern Hemisphere the same climatic influence on the incidence of the disease has in the past been observed, but the 1937 epidemic started in the winter, the first case being reported towards the end of June. Quite early it became obvious that the epidemic differed from previous ones also in the ease with which it spread from infected to susceptible, in the very large proportion of cases showing involvement of the muscles of the trunk, neck, and face, and in the frequency of bulbar forms. On the advice of the Minister of Health, Sir John Harris, M.D., the Government appointed a Consultative Council to advise as to the steps which should be taken to attempt to control the epidemic, and the Council held its first meeting when the epidemic had been in existence for one month, there having been twenty-two cases, of which four had ended fatally. We possess no effective means for the control of poliomyelitis. There is no evidence from either laboratory or field experiments that passive immunization will be of use prophylactically, and the recent efforts to discover a safe and effective vaccine with which to produce active immunity in man have not been attended with success. Even the method of spraying the nasopharynx with solutions of alum, picric acid, tannic acid, or zinc sulphate, which had given such encouraging results in experiments on monkeys, would seem powerless to prevent infection of man with poliomyelitis. Aware of this inability to combat poliomyelitis by means of prophylactic measures, specific or otherwise, the Council had perforce to rely in the main on the isolation of cases and contacts in their attempt to control the epidemic. It was of the opinion that adults would probably play but a small part in the dissemination of infection, and therefore decided to place no general restriction on the movement of adults provided they remained healthy. But an attempt was made to control any movements of children which would facilitate contact between infected and susceptible. The suburb of Ormond and a considerable area surrounding it was defined as an infected area. The closing of schools in this area was advised, as was the restriction of the movement of children both within the area and from this area to surrounding uninfected districts. Parents were advised to keep their children at home and not to allow them to go to cinemas, picnics, swimming pools, or to other places of entertainment. They were requested to report any indisposition of their children. Meanwhile the health authorities set to work to isolate actual cases and their contacts with the utmost expedition. In this they were aided by the high virulence of the epidemic and the readiness with which infection passed from individual to individual. How effective they were in this work is shown by the fact that on more than one occasion the contacts of an actual case were already isolated when they themselves developed the disease and further spread from them was avoided. Everyone, including the majority of the

parents, co-operated enthusiastically, and although the impression gained was that these measures were probably effective in slowing down the spread of the epidemic and limiting it to a certain extent, poliomyelitis eventually encroached upon neighbouring parts of the metropolitan area of Melbourne and country districts in various parts of Victoria. By the end of January some 1,200 cases had occurred, which goes to show only too clearly that in the control of a disease like poliomyelitis prompt recognition and isolation of the case and its contacts, even when supplemented by restriction of the movement of susceptibles, can only achieve a very partial success.

### VARIATIONS IN FUNCTIONAL ACTIVITY OF THE PITUITARY

Research in endocrinology goes on apace, and as contributions to this we welcome the papers in this issue by Henderson and Rowlands and by Boycott and Rowlands which deal with the assay of the gonadotropic potency of the pituitary body and the nature of the gonadotropic substance circulating in the blood of pregnant women. Assays of human pituitary tissue show that there is a reciprocal relation between the gonadotropic activity of this gland and the functional state of the gonads. After the menopause there is an increased potency of the pituitary in response to the increasing resistance of the ovary to gonadotropic stimulation. Evidence of this excessive pituitary secretion has been found in the presence of abnormal quantities of a follicle-stimulating factor in the urine, and it has even been suggested that this increased activity may be responsible for the menopausal syndrome and that the efficacy of oestrin therapy is due to its inhibitory effect on the pituitary. That such inhibitory effects may occur has been repeatedly shown experimentally, and the rationale of certain forms of administration of oestrin and of male hormone is based on this assumption. For example, oestrin has been given in cases of acromegaly<sup>1</sup> with symptomatic relief and also in Cushing's syndrome<sup>2</sup> with the object of diminishing the secretions of the basophil cells. With a like object in view oestrin in large doses was administered in cases of Graves's disease,<sup>3</sup> though with little effect, and more recently treatment with male hormone has been suggested as a means of inhibiting the supposed excessive secretion of thyrotropic hormone in this condition. It has been further suggested<sup>4</sup> that if the pituitary has been inhibited by an intensive course of oestrin therapy its "release" at the end of such a course of injections will result in an increased activity which may provide a sufficient stimulus for ovulation in certain cases of sterility associated with non-ovulatory cycles. The diminished activity of the pituitary during pregnancy is another example of the reciprocal relation between that gland and the ovary, for ovarian secretion reach a high level in pregnancy, and it is al-

<sup>1</sup> *Proc. Mayo Clin.* 1936, 11, 121

<sup>2</sup> *Endocrinology*, 1938, 22, 374

<sup>3</sup> *Lancet*, 1936, 2, 970

<sup>4</sup> *Dtsch. med. Wschr.*, 1935, 61, 1149

certainly the pituitary release at parturition when the concentration of oestrin rapidly falls which is responsible for initiating the secretion of the luteogenic hormone. Although pituitary activity is inhibited in pregnancy a gonadotropic factor elaborated by the placenta still circulates as is shown by its high concentration in the urine. Boycott and Rowlands have demonstrated that the gonadotropic factor extracted from the serum of pregnant women possesses exactly the same luteinizing property as that found in the urine. This is of considerable interest in view of the fact that the gonadotropic factor extracted from the blood of pregnant mares is not luteinizing but follicle stimulating, and forms the source of such useful commercial preparations as gonadyl and antostab.

### THE IDEA OF A GARDEN CITY

*Health and Garden Cities* is the first of a new series of pamphlets issued by the Garden Cities and Town Planning Association 13 Suffolk Street Pall Mall SW1 price sixpence. The author Dr Norman Macfadyen chairman of executive of the Association maintains that the environment which mankind requires is the most natural one possible for the circumstances under which he lives. The inevitable strain of life can be eased by good housing conditions and good working conditions together with amenities for the enjoyment of leisure freedom for proper rest and facilities for obtaining fresh food. Dr Macfadyen defines the essential idea of a garden city. It is self-contained it is planned beforehand it is a social unit independent and surrounded by an open belt of country. Some striking figures are given in support of the author's contention that life in a garden city is the healthiest known in this country under present conditions. For example the number of tuberculosis cases per thousand living is 0.38 in Letchworth and 0.574 in Welwyn the figure for England and Wales is 0.804. The rates for general mortality and infant mortality are also remarkably low in the garden cities. Indeed Dr Macfadyen maintains that if all the children in England and Wales were born under the conditions ruling in these fortunate towns some 20,000 infants would be saved every year. The pamphlet is illustrated by eight photographs of Letchworth and Welwyn Garden City showing factories houses and facilities for outdoor recreation.

### AETIOLOGY OF TRACHOMA

The discovery by Noguchi in 1927 of a very small Gram negative bacillus *Bact. granulosis* in the lesions of human trachoma and the reproduction of a granular conjunctivitis in monkeys by inoculation with pure cultures of this organism raised hopes that the long-disputed aetiology of trachoma had been solved at last. Observations by subsequent workers however failed in considerable measure to confirm Noguchi's findings and it became clear that the question of the real

causation of the disease was still in the melting pot. In 1931 Coles in South Africa drew attention to a conjunctivitis in sheep that appeared to be due to invasion with an organism of the Rickettsia group. This report suggested a new line of approach to the trachoma problem and workers—notably Busacca<sup>1</sup> in 1933 and Thygeson in 1934—were soon forthcoming who described the finding of rickettsial bodies in the conjunctival and corneal epithelium of patients suffering from trachoma. A review of the progress of investigations in this field is afforded by Foley and Parrot.<sup>2</sup> Working in Algeria they were able to substantiate the finding of tiny coccoid bodies 0.2–0.3  $\mu$  in diameter staining pale blue with Mav Grunwald Giemsa and occurring—sometimes in enormous numbers—in the epithelial cells removed by gentle scraping from the conjunctiva. In the granulation tissue they were far harder to find. They appeared to resemble closely the well known elementary bodies of Prowazek and Halburstaedter. The bodies were observed in seventeen out of eighteen untreated children in twelve out of thirty children that had received some treatment and not at all in four normal children. The name *Rickettsia trachomatis* is suggested for the causative organism in preference to the name *Rickettsia trachomae* proposed by Busacca. Interesting as these findings are it must be remembered that it is dangerous to regard every small coccoid bacillus staining with Giemsa and occupying an intracellular position as necessarily belonging to the Rickettsia group. On such characteristics some of the larger filterable viruses like vaccinia would have to be included with the Rickettsiae. Hitherto one of the essential properties of the Rickettsiae has been their insect habitat. It may be that certain Rickettsiae can be directly transmitted from mammal to mammal without passing through the intestinal canal of arthropods. Until this however is clearly established and until much more work has been carried out on their cultural metabolic and antigenic properties it will probably be wise to maintain an open mind on the exact nature of the small bodies found in trachoma.

### LYSOZYME AND THE BOWEL

Lysozyme discovered by Fleming as long ago as 1922 appears now to be coming into its own after a long period of comparative neglect. This remarkable substance which is found in large amount in the lacrimal nasal and bronchial secretions and is also demonstrable in tissues can rapidly destroy many non pathogenic bacteria and has a less pronounced effect on a few potentially pathogenic species such as *Streptococcus faecalis*. That the conjunctival sac depends for its sterility on lysozyme and that the air passages are assisted by it in destroying inhaled bacteria no one now disputes but the original claims for lysozyme went further than this. It was said to be an important factor in the resistance of the tissues generally to infection and susceptibility to its action was actually suggested as

a determining cause of non-pathogenicity in bacteria. This view was not generally accepted, nor is it to-day but a good deal of attention has recently been given to lysozyme, in the direction of studying its constitution and distribution and demonstrating its importance as a surface defence mechanism. It was shown some years ago by Findlay that the xerophthalmia of vitamin A deficiency is accompanied by a diminished lysozyme content of the tears. A series of elaborate experiments now reported by Sullivan and Manville<sup>1</sup> suggest that a similar effect occurs in the lower bowel. The lysozyme content of the colon in rabbits was found normally to be high and in vitamin A deficiency it was increased, a fact attributable to failure in its secretion. The feeding of dried apple to such rabbits reduced the content to normal, from which it is concluded that either vitamin A or the active constituent in apple, which is said to be uronic acid, is required to enable the colon to secrete lysozyme in adequate amount. The differences in lysozyme content are far from striking, the absolute maximum and minimum concentrations of the extract causing lysis in one series of experiments being no further apart than 1 in 3,200 and 1 in 12,000, a fact which may call for some reserve in interpreting the results. It may be recalled that a diet consisting exclusively of apple has been recommended in the treatment of diarrhoea in children—a paper by Birnberg on this subject was referred to in these columns some years ago. The beneficial effects of this diet were then attributed to other causes, but the recent observations on lysozyme suggest that this may be a factor. Sullivan and Manville regard it as fully established that adequate secretion of lysozyme is necessary for the protection of the colon against attack by its own flora, and suggest that "over-stimulation of mucus production with a resultant depletion or exhaustion in lysozyme output" may have something to do with the origins of ulcerative colitis. Although this is pure fancy it is an idea well worth investigating, and, indeed, if experiments such as those quoted are to be accepted at their full significance deficiency of lysozyme should command attention as a possible factor in chronic infections of all mucous surfaces.

### LIPOID PNEUMONIA

Some months ago in commenting upon several papers from America dealing with changes in the lung secondary to inhalation of oily substances, we pointed out that pathologists in this country had not so far shown any particular interest in the subject. *Post hoc* a contribution has been made by Dr J. L. H. Paterson<sup>2</sup> who has discovered eight cases of "lipoid cell pneumonia" in 813 consecutive necropsies at University College Hospital London. The histological appearances were similar to those previously described, and as with other cases reported the eight cases comprised either old people who were comatose or suffering from some chronic disturbance of the swallowing

mechanism, or, as in two of the cases, young babies. In these two babies, each aged only 2 weeks, the oily substance found in the lungs was milk. Something like a panic seems to have been created in the U.S.A. by the attention directed to the risks of oily substances used for various nasal conditions, and these have been more or less banned there by certain public health authorities. Judging from the published papers it would be as logical to ban cod-liver oil, milk, and any of the other things which have been found in the lungs, of which Dr Paterson gives a long list. He has followed up his post-mortem findings with some experimental work, the object of which was to reproduce in animals, as far as possible, lesions found in the human subject, and a large series of animal, fish, mineral, and vegetable oils have been utilized. It seems clear that "lipoid cell" pneumonia can be produced experimentally by the intratracheal administration of oil. Relatively large quantities given in a series of small doses are required to bring about a typical reaction, but it is interesting to know that in rats bronchiectasis may follow a single large dose of oil, a finding which is not recorded in association with "lipoid cell" pneumonia in man. Dr Paterson finds that the reaction is similar with all oils, but the more easily they are removed from the lungs the less severe the change. Vegetable oils, for example, are most easily removed, while liquid paraffin and cod-liver oil lead to the most severe reactions. Certain fractions of the oils produce the same reaction as the oil itself. Lecithin, for example, is especially potent and cholesterol gives very little reaction. This latest study of the matter suggests that "lipoid cell" pneumonia is an aspiration pneumonia of a chronic type, and so far as the evidence is available it would not seem justifiable to ban the administration of oily preparations via the nose or the mouth for individuals able to swallow and cough normally.

### THE VERTEBRAL NERVE

Leriche could never be accused of being an unenterprising surgeon, and his latest contribution to the surgery of the sympathetic system is at the least unexpected.<sup>3</sup> There are probably few people who know of the existence of the vertebral nerve, much less what it is and what it does. The vertebral nerve is the name given to the strand or strands of nerve fibres lying on the vertebral artery; these fibres arise by three or four roots from the stellate and middle cervical sympathetic ganglia. Distally the fibres form a perivascular plexus around the vertebral and basilar arteries and give branches to the cervical spinal nerves. It is said that stimulation of the distal end of this nerve causes constriction of the vertebral artery and its branches and also some vasoconstriction in the upper extremities. Stimulation of the central end of the nerve is said to give rise to manifestations of pain. Leriche now advocates section of the roots of the vertebral nerve for the following four objects: to diminish cerebral vasoconstriction, to diminish vasoconstriction in the upper

<sup>1</sup> *Amer. J. publ. Hlth.* 1937, 27, 1108.

<sup>2</sup> *British Medical Journal* 1933, 1, 624.

<sup>3</sup> *Ibid.* 1937, 2, 919.

<sup>4</sup> *J. Path. Bact.* 1938, 46, 151.

<sup>5</sup> *Progr. med.* Paris, 1938, 4, 113.

limb to act on the vessels of the cervical spine and to reduce spasticity in the upper limb. No cases are described but Leriche says that he has performed the operation twelve times and has obtained encouraging results in hemiplegia, Raynaud's disease and Little's disease and expects success in cases of arthritis of the cervical spine. The vertebral nerve is automatically severed at its origin in operations for removal of the stellate and adjacent ganglia and we may wonder why it should be worth while removing this relatively small part of the sympathetic supply to the head and upper extremity when all can be removed with little more exposure and greater certainty. Leriche's reason is that this new operation is less often followed by pain in the back and arm. However since the adoption of the anterior as opposed to the posterior approach to the stellate ganglion post operative pain has been a comparatively infrequent complication at all events in this country and it is to be expected that few of our surgeons will feel any disposition to change. It is also to be noted that such sympathectomy as is achieved by section of the vertebral nerve is post- and not pre-ganglionic and the new operation is thus opposed to the general trend of thought in sympathetic surgery.

### SPONTANEOUS FISSURING OF BONES

During the past five or six years a number of cases have been reported of an obscure condition of unknown aetiology characterized by what on radiological examination appears to be a series of fissures in the bony skeleton. These tend to be symmetrical in distribution involve particularly the pelvic bones and metatarsals show little or no tendency to heal and although there is in some cases a generalized osteoporosis may be unassociated with changes in the blood calcium. Early this year R. Leriche and A. Jung<sup>1</sup> recorded the case of a woman aged 38 in whom there were incomplete fissures just above the intertrochanteric line on the under surface of the neck of each femur, the left ischio pubic ramus was similarly affected. Latent tetany was thought to be present in association with a lowered calcium content of the blood. This patient sustained a fracture of the right forearm which healed normally, there had also been nervous symptoms and pain in the buttocks and thighs. She appeared to benefit from ultra violet irradiation and the administration of vitamin D, calcium salts and parathyroid extract. Pierre Lombard and Henry Tillier<sup>2</sup> report in detail a similar case that of a man who died in 1933 at the age of 26 and had multiple bony fissures. His parathyroids were explored in February 1932 with a negative result, and at necropsy only normal parathyroid tissue was observed. These writers find it difficult to say whether the condition is a distinct entity or whether it is common to different bony dystrophies. American<sup>3</sup> and German<sup>4</sup> authors have seen similar cases and last year J. C. Leedham Green and F. Campbell Golding<sup>5</sup>

recorded a case in this country in a woman aged 24 who had fissuring of both the horizontal and ascending pubic rami and of the first and second metatarsals of either foot. Like other writers they point out our ignorance of the origin and nature of the fissures and of their treatment. They suggest that the condition should be called osteoporosis melolytica but for the moment the term 'spontaneous fissuring' would seem preferable.

### LORD HORDER'S PORTRAIT

View Day at St Bartholomew's Hospital on May 11 was the occasion of a ceremony of a kind which does not often occur. A large gathering in the Great Hall witnessed the presentation to Lord Horder of his portrait painted by Sir William Nicholson. The presentation was made by Lord Stanmore until lately treasurer of the hospital on behalf of a large number of the staff and other friends. Lord Horder accepted it in a speech happily combining wit with wisdom; he observed that no man can judge himself and he must be content to be judged by his friends. That they had considered him worthy of this distinction was a tribute which he greatly valued. He then presented the portrait to the hospital where it is to hang in the Great Hall in company with that of Paget Abernethy, Bowlby and other illustrious predecessors. It was accepted by Mr George Aylwen the present treasurer in a speech of tribute to Lord Horder's career and his services to St Bartholomew's. The portrait makes a striking contrast with those already in the hall and may well mark a change in style of which the future will in time provide more examples. The older portraits are large as life or larger, smooth, meticulous in detail and warm in colour. In this the only striking colour is that of a peer's robe which is cast over another chair behind that in which the subject is seated. The figure being full length and a good deal of the canvas occupied by fore and background its scale is small. The likeness is a fine one although perhaps a little on the grim side and lacking the twinkle of humour which many would have liked to see in it. The portrait will be on view in a public exhibition before being finally hung at St Bartholomew's.

We regret to announce the death of Sir THOMAS FLITCROFT who was for ten years chairman of the Bolton Division of the British Medical Association and took a keen interest in local public affairs.

The Right Hon. Walter Elliot D.Sc. F.R.S. who succeeds Sir Kingsley Wood as Minister of Health in the Cabinet reconstruction this week is the second medical man to hold that office. Lord Addison M.D. F.R.C.S. was the first Minister of Health—from 1919 to 1921. Dr Elliot graduated in medicine at the University of Glasgow in 1913.

# SURGICAL PROCEDURES IN GENERAL PRACTICE

*This is one of a series of articles contributed by invitation*

## HEARING AIDS IN GENERAL PRACTICE

BY

F. J. CLEMINSON, M.A., M.Chir., F.R.C.S.

If the physical intensity of a sound is increased ten times it is said to be increased by one *bel* (this name being in honour of Alexander Graham Bell, the inventor of the telephone). If the increase is a hundred times it is by two bels, and if a thousand times by three bels, and so on. For instance, the average noise in a very quiet room is two bels—that is, the noise is one hundred times as intense as that which would be just perceptible. A bel is divided into ten *decibels*, and a decibel is now recognized as the standard unit for the expression of differences in sound intensity.

### Testing for Deafness

The pure-tone audiometer is an instrument for testing the acuity of hearing both for air and bone conduction, for pure tones at octave intervals over the greater part of the entire auditory range. At each pitch the sound is slowly diminished

in intensity till it just ceases to be heard by the patient, who signals the exact moment by pressing a button. In this way curves are obtained for each ear for bone and air conduction, the results being recorded on a chart such as that illustrated here (a modification in monochrome of the chart used by Dr Kerridge in the hearing aid clinic at University College Hospital). The results are shown for one ear only, for clearness' sake. The zero line (thick) is horizontal and represents the threshold for normal persons in a silent or sound-proof room. The continuous curve represents the threshold for normal bone conduction. The curve marked by bars registers the patient's air conduction, and the dotted line his bone conduction. The curve shows that at the frequency of 512 cycles per second (C) the patient did not hear by air till the note's intensity had been increased by 40 decibels above the normal threshold—that is, until it had been made 10<sup>4</sup> (or 10,000) times stronger than necessary for a normal hearer.

The other form of audiometer in common use consists of a gramophone which reproduces spoken numbers, it shows the level in decibels above the normal threshold, at which speech becomes *intelligible* (not merely *audible*) to a deaf patient. In this form of audiometer the normal threshold has been determined in a quiet (but not sound-

proof) room—one in which there would be about 20 decibels of noise. Hence a patient who has an average loss of, say, 50 decibels over the important speech frequencies (200 to 2,000 cycles per second) in a *pure-tone* audiometer test would in a *speech* audiometer test have a loss of only 30 decibels—an apparent discrepancy which is at first confusing.

The only excuse for this brief acoustic preface is that, for some readers, it may clear up a certain degree of vagueness in their ideas about units and measurements, we are now free to pass on to the subject of hearing aids. It is difficult for those with normal hearing to realize how speech perception is affected by deafness. If, owing to some fault on the telephone, no frequency

above 1,000 cycles per second could be transmitted a normal hearer would probably say, "I can hear the voice but cannot make out the words," and would at once realize what the deaf mean when they use the same phrase. If the transmitted frequency could be raised to 1,000 cycles intelligibility would be greatly improved, but even then different voices could not be distinguished one from another. A further

Chart showing bone- and air conduction curves obtained in testing for acuity of hearing by the pure tone audiometer

rise to 2,000 cycles per second would allow familiar voices to be recognized with ease, more of their characteristic harmonics being reproduced. In this case the telephone engineer would have done for the normal hearer what the manufacturer of hearing aids aims at for the deaf, and in this aim he has very largely succeeded especially since the invention of the midgap thermionic valve.

### Non electrical Aids

The earliest aid (going back at least 250 years) was a trumpet or tube, and such an aid has still many advantages. It is cheap to buy, costs nothing to maintain, has no "endogenous" background noise, and tends to emphasize the upper end of the scale. It is therefore useful in internal ear deafness—for example, for the people—in which the greatest loss is always in the higher frequencies. There is little distortion, voices sound natural, and it is often the most suitable aid for moderate loss of hearing. These non electrical aids are made in various forms—for example single or double auricles, "banjo" horns, flexible conversation tubes, parabolic reflectors with collecting tubes leading to the ear from the focus. Auricles are more popular with women than men because they can be concealed.

# HEARING AIDS IN GENERAL PRACTICE

(4) MODE OF WEARING A PAIR OF AURICLES (F C Rein & Son)

The earpieces of this binaural adjustable auricle can be moved backwards, forwards inwards or outwards to suit the direction of the meatus. The auricles are held in position by a light adjustable head spring. The instrument is built in a number of graded powers and special models are available for children.

(1) "PERCEPTON" VALVE AID

Crystal microphone. Selective amplification obtainable by the insertion of filters. Three stages of amplification. Bone or air conduction. Made to resemble a Kodak camera. Dry batteries used.

(3) MICROTELEPHONE TYPE HEARING AID (F C Rein & Son)

(Total weight complete with battery 7½ oz.)

The transmitter or microphone (A) is worn by the male user under the necktie or by the female user similarly under the clothing. Volume control can be fitted. (B) The midget flesh tint self retaining receiver. (C) Watch pattern disk receiver interchangeable if desired with midget receiver. Proximal side down. Head band not shown. (D) Small dry pocket battery.

(5) PETO-SCOTT "MAXADE" (wearable model)

The three units are from right to left: (1) amplifier with 3 valves and built in crystal microphone, (2) low tension cell and (3) high-tension battery. Small earpiece to fit meatus.

## HEARING AIDS IN GENERAL PRACTICE

(6) MULTITONE ELECTRIC CO V P MODEL  
with "Book" Container

(A) Amplifying unit (3 valves) (B) Flexible high tension battery (C) Dry low-tension cell (D) Crystal microphone Earpiece not shown The contents can be removed easily and disposed about the person

(8) VERNON-SPENCER  
"FULL RANGE"

3-valve Model VS1 (7½ inches by 3½ inches by 1½ inches) with crystal microphone and crystal earpiece

(2) SONOTONE AUDICLE (451)

A Transmitter—Contains two microphones back to back Non directional—picks up sound equally well from every direction No holes in transmitter, sound enters at side

B Amplifier—Selective amplification obtainable by the insertion of different booster chambers Sound filter to suppress "staccato" sounds—for example clatter of knives and forks on plates

C Oscillator—Supplied in different pitches Large surface to oscillator to fit mastoid bone Both sides of oscillator can be used One side loud the other side soft

(7) MODEL C8 AMPLIVOX

The model C8 Amplivox with crystal microphone, three-stages valve amplification all dry battery working

hair and coloured to match it. Auricles can be held in place by a head spring but the others of this class leave only one hand free and cannot be used at work. The conversation tube is said to produce an amplification up to 5 decibels, and even auricles can average 12 to 15 decibels. Next to the conversation tube the binjo horn is perhaps the most efficient.

### Electrical Aids

Electrical aids in their simplest (and oldest) form are merely portable telephones that can be worn on the person. They are well known and need little description. The microphone is of the carbon granule or dust type and the granules may be larger or smaller, while the carbon diaphragm may be made of hard or soft carbon. The earpiece or receiver may be small and be worn in the ear, or it may be large (and more efficient) and be held closely to the ear by a head spring. The cell is usually of the 3 volt dry type and is carried in the pocket. Except in the carbon dust type there is often a large amount of instrumental background noise but in middle ear deafness especially when paracusis is present this is not so objectionable as in nerve deafness. Recently the receiver has been so modified that a small vibrating surface can be placed directly on the mastoid bone so that the sound reaches the inner ear by bone conduction. This

by-passing of the middle ear is particularly successful in cases of middle ear deafness with a fixed or almost fixed stapes. Bone conduction aids need more current than the simple microtelephones and are fitted with an amplifier which in some cases is of the valve type. In my experience bone-conduction aids were disappointing in their early stage when the vibrator was merely a small button apt to slip out of place and by no means so efficient or comfortable as the present type. In their original form they were found to be the most suitable aid in only about 3 per cent to 4 per cent of my cases but in their improved form the percentage is far higher than this and many patients prefer their quality of voice reproduction.

In the Medical Research Council Report No 219 (*The Use of Hearing Aids*) somewhat untavourable views are expressed on bone conduction aids. I think it very doubtful whether such views would be supported now by the experience of most otologists: they certainly seem to be at variance with our experience in the hearing aid clinic at the Middlesex Hospital. It is unfortunate however that the variety I prefer is rather too costly to be available in every case for which it appears to be most suitable.

### The Valve Amplifier

The third and most recent class of hearing aid is the valve amplifier. These were formerly large and heavy, and were made in the form of a box but now they are much smaller and some manufacturers have divided them into two or more parts so that it is possible to carry them easily about the person or in a bag. In some makes the microphone is separate and can be worn in the button-hole like a flower or under the rock. The valves may be two or three in number of the midjet valve type and are very reliable. Some makers provide not only a volume control but also a tone control whereby the relative volume of the upper and lower tones in the amplified voice can be varied and each patient can keep it in the position in which his friends' voices sound most natural. This is a great advantage. Moreover the amplification in some models is as much as eighty decibels. The low tension cells tend more and more to be of the easily obtainable

ever-limp type. The high tension batteries usually have a voltage of about 30 and last some months. The earpiece is commonly of the large and more efficient kind held over the ear by a spring. Small receivers which fit into the meatus can be supplied but these though less conspicuous are also less efficient. The microphone may have a carbon diaphragm. A crystal microphone increases the price by some pounds but greatly diminishes that part of the background noise due to the instrument itself. Some instruments have a crystal earpiece also and are particularly quiet. One maker has an automatic volume control which prevents for example a hand-clap near the wearer from sounding loud enough to startle him. He has also introduced a special device whereby while one ear receives the whole output of sound high and low only the high tones are allowed to reach the other. This involves wearing two earphones. Its purpose is to reduce what is called the masking effect of low tones on high tones. The synthesis is probably carried out in the cerebrum.

All valve instruments tend especially to amplify the upper end of the scale and therefore with a crystal microphone to minimize instrumental background noise they are particularly suitable for cases of senile or other internal ear deafness because they tend to compensate for the disproportionate loss of high tones. Hence it is no longer true that for senile deafness an electrical aid is useless: on the contrary it is often most valuable.

There are many ways in which the sound output of a hearing aid may be varied. But when all is said and done it remains quite impossible to prescribe aids for loss of hearing in the same accurate way as lenses can be prescribed for changes in refraction. In the microtelephone aid the situation of the peak or amplification can be influenced by the degree of hardness of the carbon diaphragm and to some extent by the material of the earpiece diaphragm but broadly speaking it is the middle part of the range of pitch more than the upper which is amplified and this fact together with their greater tendency to record background noise makes them unsuitable for senile or other forms of nerve deafness for which either a non electric aid or a valve aid with crystal microphone and tone control is most suitable. Bone-conduction aids should be tried more often in middle-ear or mixed deafness especially where there are signs of limitation or movement of the stapes. This condition may occur as the result of otosclerosis, chronic middle-ear catarrh or the fibrotic changes following suppuration.

### The Medical Man and the Deaf

How can a medical man do his best for a patient who needs an aid? In the first place it may be difficult to persuade him (or more often her) to try one. One objection after another may be made. To use one will proclaim my deafness to the world but of course his world knows it only too well already and would welcome anything to make social intercourse less exhausting. I can hear well enough if people will only speak distinctly but everybody mumbles nowadays. He must be shown that the fault lies in his own ears and then an appeal to his better nature may succeed if he can be made to realize how tiring it is to talk when the voice has to be raised and almost every remark repeated at least once.

I have no friends now—people avoid me so why should I bother? his friends will come back when they find they can talk to him easily. I am afraid it will make my hearing worse there is no evidence whatever that an aid makes hearing worse but, as when a short-

sighted person who takes to spectacles may realize how imperfect his vision was without them, so the deaf man with an aid may wonder whether his hearing really could have been so bad as he now knows it to be "I shall lose my employment if it is known I am deaf" his employer almost certainly knows it already, and he will be less, not more, likely to lose it if he can hear what he is told. Deep-rooted vanity, perhaps unconscious, is the greatest obstacle. A charming but rather masterful old lady was once persuaded by her friends to consult me, and as conversation was difficult she was induced to try a valve aid 'just to see'. Everything seemed to be going well and the conversation had become quite brisk when it suddenly came home to her that the apparatus was a great help. She instantly removed it, stiffened perceptibly, abruptly closed her mind to its virtues, and said it was "quite useless, very unsightly, and she would never dream of wearing it". "But what about your family, who tell me they have almost to shout at you?" "Well, they must go on shouting."

Without special knowledge of the subject it may perhaps be inadvisable for the medical man to name any particular hearing aid. The responsibility can usually be shifted to one of greater experience, and if it is impossible to arrange a private consultation the patient can be referred to the aural department of a good hospital or, better still, to a hearing-aid clinic such as those now established by Dr Kerridge at University College Hospital and, more recently, following the same lines, by the Ferens Institute of Otology, Middlesex Hospital. In time every hospital will probably have one. At such a clinic the patient will have an audiometer test done and then be tested with the most appropriate of the series of hearing aids kept for the purpose. A home trial of the most suitable one, if any, will be arranged, and the almoner will discuss with the patient the best means of payment and tell him what organizations may be prepared to help him and to what extent. If after trial the instrument proves satisfactory it can be obtained through the almoner at a specially reduced price. A number of the leading manufacturers have been kind enough to send specimens of their products on permanent loan for testing patients at the hearing-aid clinic at the Middlesex Hospital, they are Messrs Amplivox, Multitone Electric Co., Peto Scott, F. C. Rein and Son, Sonotone, and Vernon-Spencer, without their ready help it would have been difficult to establish the clinic. So that the reader may have an idea of the range of hearing aids and know what they look like, illustrations of various models have been included in this article.

#### Advice to the Deaf

Patients who wish to go direct to a dealer will find the following advice excellent. It is from a paper (*British Medical Journal* 1935 1, 1314) by Dr Phyllis Kerridge, whose work and publications on the subjects of deafness and hearing aids are so well known and so valuable.

- 1 Take a friend with you, and listen to a voice you know as well as to that of the demonstrator.
- 2 Move about with the instrument on.
- 3 Switch the battery on—if it is an electrical aid—and listen when nobody is speaking, both when you are sitting down and moving.
- 4 Try more than one make of instrument of the type you favour.
- 5 See that the carpiece fits really comfortably. They can easily be adjusted to individual requirements.
- 6 Try a large carpiece as well as a small one.
- 7 Insist on a home trial without obligation to purchase.

8 When at home listen to general as well as to individual conversation.

9 See how long the battery (if any) lasts you, and calculate the cost of upkeep.

10 Do not wear a new instrument for too long at first. You will probably make your ears tired, and therefore seem more deaf.

11 If, after trial of an instrument, you can hear satisfactorily with it and procure one and subsequently cease to be able to hear with it, or if adventitious noises develop do not conclude that you are getting deafer or that the instrument is no good. Send it to be overhauled. A simple repair or renewal is probably all that is necessary.

#### Lip-reading and General Information

A doctor should strongly advise patients with chronic deafness to have lessons in lip reading and to practise it most assiduously. It is an invaluable accomplishment, readily attained in earlier life but far more difficult to learn after 50. For information about lip reading classes or teachers, application should be made to the National Institute for the Deaf, 105, Gower Street, W.C.1 (secretary, Mr A. J. Story). This organization is of the greatest use. It supplies literature in the form of leaflets, pamphlets, and books, gives information about the employment of the deaf, choice of aids, and the danger of the exploitation of the deaf by unscrupulous dealers. To minimize this a list is kept of those dealers and manufacturers who agree, among other things (1) to permit no representative of the firm to pay unsolicited visits to clients' homes, and (2) to allow a reasonable home trial of their apparatus for a fee which does not exceed 5 per cent of the purchase price for non-valve and 7½ per cent for valve aids per week. This fee is deducted from the cost if a sale results. Patients should be urged to keep to this list in making their choice.

#### ROYAL MEDICAL BENEVOLENT FUND

At a recent meeting of the committee three annuitants were elected, the total amount voted being £86. In addition thirty-eight beneficiaries (including eleven new applicants) were awarded grants amounting to £947. The following are particulars of three cases.

Widow, aged 64, of M.R.C.S. who died in 1916 aged 43. The widow has had a salaried post in social work for many years but owing to the closing down of the association, lost her employment in December, 1937, and at the age of 64 cannot find fresh employment. Her two children, aged 34 and 30, are unable to contribute to her support. The Fund voted an allowance of £1 a week for six months, and is seeking the co-operation of other charitable societies to help this most deserving applicant.

Daughter, aged 60, of M.R.C.S. who died in 1914 aged 76. The daughter has helped her mother to run a boarding house since 1914, and they have just managed to maintain themselves. The mother is now 83, and all the work falls on the daughter who does the cooking for the establishment as well as looking after her mother. For years she has had a hard life and a struggle to make ends meet, with no money for extras or a holiday. The Fund voted £20 to enable the daughter to have a holiday and rest.

Widow, aged 66, of L.S.A. who died in 1915 aged 52. She has an invalid daughter. The widow since her husband's death supported herself and had educated her daughter by success in running a boarding house until 1933 when circumstances forced her to give up. Recently she has suffered from a duodenal ulcer which necessitated nursing home treatment. Her own and daughter's illnesses have been a great drain on her resources and the money she had put aside has been used up. Her only income is now £60 and the invalid daughter is able to earn £26 per week by teaching painting. The Fund voted an allowance of £1 a week for six months when the case will be reviewed.

New annual subscribers are urgently needed by the Fund. Cheques may be sent to the Honorary Treasurer, Royal Medical Benevolent Fund, 11, Chandos Street, Cavendish Square, London, W.1.

## WESTMINSTER HOSPITAL MEDICAL SCHOOL

### OPENING OF NEW BUILDING

The new medical school at Westminster Hospital was opened by the Earl of Athlone, Chancellor of the University of London on May 12. With the new nurses home recently opened by Queen Mary it forms a large block on the west side of St John's Gardens, Horseferry Road, while the main hospital building is in course of erection on the east side. It is expected that the hospital will be opened by the King and Queen in April 1939 when the old site in Broad Sanctuary will pass into the hands of new owners who propose to erect thereon a Gothic building harmonising with the architecture of Westminster Abbey immediately opposite. The cost of the rebuilding of the hospital nurses home and medical school is estimated at £520,000. This includes the acquisition of the sites. A sum of £14,000 is required to complete the cost of the new school.

### Planning and Equipment

The medical school, a building of eight floors, embodies many new ideas in planning and equipment. On the ground floor is a students common room and refectory as well as other rooms for the cultivation of the social side of student life. The main lecture theatre occupies a part of both the ground and the first floors. It seats 250 who are all accommodated in special chairs with panels for notebooks and it contains a film projector and modern epidiascope. Most of the first and mezzanine floors is occupied by the museum and library beautifully panelled in Australian walnut and teak and with special lighting arrangements suitable to each department. The museum contains 3,000 specimens a collection which has become of great value with constant replacement. The library which has additional space in its galleries for future expansion is provided with the latest edition of every standard work and an excellent choice of monographs and periodicals.

The second floor includes the main classroom with the desks so arranged as to give an uninterrupted view of blackboard and screen from every seat and each student's place is provided with microscope and equipment for experimental work. Adjoining the main classroom is a preparation room and a small lecture theatre in which again a cinematograph projector is available. On the third and fourth floors is a first rate suite of laboratories and workshops in which the principal pathological work of the hospital is to be carried out. The main clinical laboratory named after John Burford Carlill, a generous benefactor is divided into cubicles for individual workers. On the higher floors are rooms reserved for special examinations and tests on the living subject, small laboratories for urgent pathological investigations, arranged in close

association with the wards and operating theatres of the hospital and a large biochemical laboratory with comfortable little rooms adjoining where out patients may be received for special tests without the necessity of entering the hospital itself. There is also a physics room a laboratory for the measurement of radium emanation—Westminster Hospital being a special centre for radium treatment—and in the basement a vibration proof laboratory for the testing and use of delicate instruments in clinical and research work. A room is set apart for training students in operative surgery. An anatomical museum and a special x-ray room for post mortem specimens have been installed. Post mortem examinations are to be conducted in a room designed by the staff in which the air is ozonized and filtered. On the recreational side a gymnasium, squash rackets court and shower baths are provided and flat roof spaces afford opportunities for leisure or study in the open air. One interesting feature is the assignment of a room for old Westminster Hospital students whose visits at any time will be welcomed.

The old school accommodated from ninety to ninety-five students; the new one will accommodate at maximum capacity 200 but 120 at any one time are expected.

The main hospital building, on the left of the drawing will be completed in 1939.

### The Opening Ceremony

Dr ADOLPHE ABRAHAM, Dean of the School of Medicine in welcoming the Chancellor of the University when he arrived to open the new school said that the magnificent new building was due to the wisdom and generosity of men of vision who had recognized the importance of the student and had

appreciated that side by side with the treatment of the sick proceeded the training of the doctor of the future. He placed on record the school's lasting gratitude to all who had made possible the existence and equipment of the building not least among them being the University of London.

The EARL OF ATHLONE in declaring the school open congratulated the authorities on their success in raising the large sum required to provide a school not only worthy of the hospital to which it was attached but also fully adequate to the needs of modern medical education. The benefits of such a school connected with an institution for the healing of the sick were threefold. First the existence of a medical school made it possible for the hospital to obtain the services of physicians and surgeons of distinction and eminence. Secondly the continual presence of medical students vigilant critics of what they saw and heard kept the teaching staff up to the mark. Thirdly and most important the existence of a medical school connoted not only the treatment of the patients in hospital but also the steady day to day compilation of accurate clinical records and unceasing research into the cause and treatment of disease. The provision of the building he was opening had removed the handicap of accommodation inadequate to the requirements of modern

medical education. It was a source of satisfaction to the University of London that the school's facilities for teaching would be so greatly enhanced. The University had made its usual contribution with the best of good will and in the desire to acknowledge the great efforts that had been made by the school's benefactors and governors, and by the medical, surgical, and scientific staff. The results of their efforts were evidenced in the well-planned and appropriate accommodation provided in the new Westminster Hospital Medical School which he had so much pleasure in declaring open.

Mr HUGH M CLOWES chairman of the School of Medicine, speaking on behalf of the governors of the hospital, expressed thanks to the Chancellor for opening the school of which all concerned were so proud. He was glad to be able to report that as a result of the generosity of their friends only £14,000 had yet to be found out of the £65,000 required for rebuilding. In the last few days the figure had been reduced from £15,000 to £14,000 because of the generous gift of £1,000 by a prominent citizen of Westminster who wished to remain anonymous. And in addition to the contributions he had already made Sir George Tilley had promised a further £600 towards the sum still to be found. The hall in which the opening function was taking place bore the name of "Meyerstein." It was difficult to express adequately the gratitude due to Sir Edward Meyerstein, whom it was a pleasure to all to see on that occasion. In conclusion Mr Clowes paid a tribute to the members of the building committee, and mentioned especially the names of the indefatigable chairman, Mr Bernard Docker, Mr Rock Carling, senior surgeon, Mr J D C Couper, Dr Pulvertaft, director of the laboratories, and Mr Peter Adams, architect.

Sir GEORGE TILLEY, chairman of the Medical School Rebuilding Fund Appeal Committee, seconded the vote of thanks, and earnestly expressed the hope that he might receive further support in the final effort to secure the completion of the fund. At any rate, he had promised not to relinquish office until the remaining £14,000 had been secured.

The opening proceedings ended with a prayer of dedication by the Dean of Westminster, following which the Chancellor and guests were shown over the new building.

## THE TAVISTOCK CLINIC

### EFFECTIVE RESULTS OF TREATMENT

The annual meeting and luncheon of the Tavistock Clinic were held at the Cafe Royal on May 9. Lord ALNESS (chairman Child Guidance Council), the newly elected chairman who presided at both functions, paid a tribute to his predecessor, Sir Henry Brackenbury, who for eight years had shown unflagging zeal and untiring energy in his efforts on behalf of the clinic.

#### Nervous Disorders in Industry

The EARL OF FEVERSHAM (Parliamentary Secretary to the Minister of Agriculture and Fisheries) endorsed this tribute to Sir Henry Brackenbury who before he joined the council of the Tavistock Clinic had recognized the great importance of psychological medicine and had done much to familiarize the whole of the medical profession with the subject of psychology. Lord Feversham went on to say that as a probation officer in years gone by he had come to know that crime and delinquency were in many instances only an expression of deep-seated psychological causes. It was then that he had come into contact with the Tavistock Clinic, and

realized that it was doing more than any other body to meet a national need. He now found himself at the Ministry of Agriculture dealing with the subhuman species, but he still held that to see nature in the raw one must turn to man. Those engaged in industry undoubtedly knew that, in these days of high speed and pressure, industry was a mushroom bed for breakdown and inefficiency. The recent researches by Professor Millais Culpin on behalf of the Industrial Health Research Board and of Dr J L Halliday of the Regional Medical Officers Department of Health for Scotland showed that there was a formidable percentage of nervous illness amongst the working population. Obviously, if the much needed further contribution was to be made to all branches of occupational disorder, the work for which the Tavistock Clinic stood must develop at an even faster rate than during the past eighteen years of its life. It was necessary not only to get general practitioners in the provinces to have a higher regard for the problems involved but also to persuade the public to contribute an ever increasing sum towards the maintenance of the work of the clinic.

Mrs I M SIEFF a member of the council of management, said the records of the clinic showed in regard to patients that of 1,000 cases followed up over a period of six years 55 per cent had been permanently relieved—no mean achievement for a branch of medical science as yet in the pioneering stage. And it was always necessary to bear in mind that a neurotic individual must cause a feeling of strain and anxiety in the family circle, which strain and anxiety might lead to physical breakdown of one or more members of the family. It was hoped that the research department of the clinic might one day discover a method of short circuiting the present somewhat protracted method of psychological teaching, and thereby make possible the treatment of a larger number. The wiser handling of children from the psychological point of view had shown itself in the springing up of over thirty child guidance clinics. The Tavistock Clinic was engaged in an investigation into nervous illness as affecting the industrial worker. The speaker hoped it would eventually investigate the question as affecting the employer and managerial classes for it was just as important that they should be harmoniously balanced.

#### Scientific Handling of Psychoneurosis

Dr J R REES medical director of the clinic, said that the waiting list was again closed with 400 names on it, and asked the audience to think quietly to themselves what was to happen to some of those 400 before they could undergo treatment in perhaps a year or eighteen months' time. How many would have committed suicide and how many would have had to be certified? Such questions involved problems concerning not merely the work of the Tavistock Clinic but the wider problem of the psychoneurotic in the country at present so inadequately provided for. It was a lamentable fact that only about one medical practitioner in 150 had experience of the scientific handling of psychoneurosis. About one third of all illness was due to neurosis, and 31,000,000 working weeks per year were lost to industry from that cause. To say nothing of the inefficiency arising from neurosis. Obviously the training side of the clinic's work was most important. The clinic now provided 25,000 hours of treatment a year, and as it had been able to help those who had been drawing sickness pay, in some cases for nine years, it was doing something of economic value to the country as a whole. A psychological approach which could offer explanation and treatment of nervous illness must eventually lead to the prevention of a large number of disorders which were obviously not always attributable to neurosis. Whether one viewed the subject from the economic or the humanitarian point of view or as a general problem of national fitness, it was important that those engaged in the clinic should be enabled to make a steadily better contribution to the solution of the problem.

Sir HENRY BRACKENBURY reporting on the year's work of the annual meeting which preceded the luncheon stressed three features which had characterized the work of the clinic throughout its existence: its continuity, its variety, and its

## INTERNATIONAL ACADEMY OF POST-GRADUATE MEDICINE

In 1909 an International Committee for Medical Postgraduate Work was formed during the sixteenth International Congress of Medicine in Budapest. Professor Waldeyer (Privy Councillor) of Berlin was elected president. The Italian delegate to that congress was the great scholar and statesman G. Bacelli, who delivered a magnificent address, *La via delle vene aperta ai medicamenti e ioici*.

The first session of the International Committee was held in 1913 under the presidency of Sir Donald MacAlister during the seventeenth International Congress of Medicine in London. The report of this session was not, however, published until 1918, under the editorship of Hofrat Professor E. von Grosz and Professor C. Adam. The war and post-war period prevented any further convocation of the committee. The members of the executive commission are almost all of them dead, and very few of the committee are still living. Professor von Grosz had intended to convene a conference in Budapest in 1933 with the idea of reorganizing the original committee. At the request of the German representatives this conference was postponed, since the Third Reich had only just been founded at the time.

The German State Organization for Postgraduate Medicine in August, 1937, convened a Congress for Medical Postgraduate Work in Berlin, and this was attended by delegates from forty-four nations. It was decided to found an International Academy of Postgraduate Medicine. A preparatory committee was elected at this congress, consisting of the following: Professor Adam, Director of the Kaiserin Friedrich Haus, Berlin; Dr. Blome, mandated by the Reichs-medical Leader of postgraduate work, Berlin; Privy Councillor Professor Borst, Munich; Professor Raffaele Bastianelli, Rome; Colonel A. H. Proctor, Dean of the British Postgraduate Medical School, London; Professor Roussy, Dean of the Medical Faculty, Paris; and, more recently, Rector of the University of Paris. This committee convened a special congress in Budapest for the ceremonial constitution of the Academy. The Royal Government of Hungary and the city of Budapest sent a formal invitation to the Academy to hold the congress in that city. One hundred and six delegates attended and twenty States were represented.

### Aims and Machinery

On April 23, 1938, the International Congress appointed an International Committee and approved the constitution of the International Academy for Medical Postgraduate Work. As set forth in the constitution the objects of the Academy are:

- 1 To arrange for an International Congress on Postgraduate Medical Education to be held every four years
- 2 To render readily available to all nations the most recent results of scientific research and medical experience
- 3 To provide for postgraduate training of doctors in all countries and to furnish information to authorities and organizations working in the field of hygiene and public health

The Academy intends to pursue this aim by all expedient means—as for instance, by the exchange of teachers and students by planned tours of study, by the exchange and publication of literature. The headquarters of the Academy have been fixed in Berlin.

The International Committee consists of the delegates from the countries participating. The Presidential Board is composed of the President, five Vice-Presidents, and the members of the permanent bureau. The Vice-Presidents

each represent a different country. Professor Borst was elected President, and the following as Vice Presidents: Professor Raffaele Bastianelli, Rome; Professor M. Tieffeneau, Dean of the Faculty of Medicine, Paris; Colonel A. H. Proctor, Dean of the British Postgraduate Medical School, London; Professor Olivecrona, Stockholm; and Professor Arcze, Buenos Aires. Dr. Blome was elected President of the Permanent Bureau, with Professor Adam of the Kaiserin Friedrich Haus as General Secretary and Dr. Putz as Treasurer.

### Opening Session in Budapest

The opening session of the Academy took place in the Ceremonial Hall of the Hungarian Academy of Sciences. In addition to the delegates of the various countries, representatives of the Royal Hungarian Government, of the Municipality of Budapest, and of the universities of Hungary were present. The opening speech was delivered by Professor Borst of Munich. Then came the representatives of the Hungarian Government, followed by the Mayor of Budapest, Dr. Karl Szendy. After this there were speeches from the delegates of other countries: Professor Bastianelli of Rome, Professor Leriche of Paris, and Colonel Proctor of London. Dr. Blome reviewed the tasks and aims of the International Academy, and Professor Borst concluded with an address on "An Ideal for the Doctor."

The scientific proceedings took place on April 25, 26, and 27 in the Semmelweis Hall of the Royal Medical Society. Papers were read by Professor Olivecrona, Professor von Bergmann, Professor Szent Gyorgyi, Professor Leriche, Professor Bastianelli, and Dr. A. S. Parkes. Receptions were given by the Government, the Municipality of Budapest, and the Central Committee for Medical Postgraduate Work, as well as by the National Museum and the Royal Ministry of Agriculture. The President of the Academy gave a banquet for the members of the International Committee. The Balaton Committee invited the members on a trip to Balatonfüred. Several members also visited the provincial universities.

The establishment of the Academy, it is hoped, will benefit the health of every nation and simultaneously advance international friendship and collaboration among the medical profession in all countries.

The Duke of Gloucester presided at the statutory meeting of the Council of the British Red Cross Society on May 12. A report was received in regard to the XVIIth International Red Cross Conference, to be held in London from June 10 to 24, of which particulars appeared in the *Journal* of May 7 (p. 1022). A point of particular interest in a very full agenda is a proposal by the Society for the merging of the Geneva and Hague Conventions into one comprehensive Convention, dealing with land, sea, and air warfare. The Society has continued to assist in Red Cross work in Spain. At the beginning of the year, owing to financial stringency, the International Red Cross Committee asked national societies to undertake the preliminary work in connexion with inquiries regarding prisoners and refugees in Spain emanating from their own countries, and the British Red Cross Society is carrying out this work. In China the Society is co-operating with the Lord Mayor's Fund to make provision for the relief of the sick and wounded and to bring some relief to the suffering and destitute. At home, progress continues to be made in special training and organization to co-operate with the Government in preparation for defence against air warfare. The clinic for rheumatism continues to work at capacity and during 1937 gave a total of 145,922 treatments. The Blood Transfusion Service meets an urgent need and calls on the London service alone amounted in 1937 to 5,622.

## Reports of Societies

### RADIUM FOR CARCINOMA OF THE VULVA

A meeting of the North of England Obstetrical and Gynaecological Society was held in Sheffield on March 18. Dr FRANK ELLIS, medical director of the Sheffield Radium Centre, read a paper on the radium treatment of carcinoma of the vulva. Before the meeting he demonstrated a series of cases in which complete healing of primary vulval growths had been obtained without necrosis by the use of uniform irradiation.

Dr Ellis said that the radium treatment of carcinoma of the vulva had been generally discredited in the past owing to the high incidence of both radium necrosis and local recurrences. The introduction of certain modifications of the usual technique, with the object of obtaining a more uniform irradiation of the growth had transformed the outlook for radium therapy, so that in his opinion it could now compete with surgical measures in the management of this condition. The first and perhaps the most important, modification had been the insistence upon nursing the patients in the same posture as was adopted for the insertion of the radium. The radium needles then retained their proper spatial relationships throughout the treatment and undesirable crowding after the return of the patient to bed had been avoided. Where the growth was at the anterior end of the vulva the needles were inserted with the patient in the supine position, where the growth involved the posterior end of the vulva the left lateral position was adopted, the patient being nursed in the same position. If the entire vulva was involved the needles were inserted and nursing carried out with the patient in the lithotomy position.

When needles had to be placed on the surface of the growth sorbo rubber pads were used to protect adjacent skin surfaces and to keep the needles at a known distance from the growth. After the needles had been inserted a perforated rubber dressing was placed over the vulva and eusol irrigation practised twice daily, an indwelling catheter was necessary. Dr Ellis had found his results were best when all the needles were placed 1.5 cm apart. The theoretically better distribution of the radium with the periphery of the growth receiving half as much radiation again as the centre—that is with the peripheral needles only 1 cm apart—had not given such good clinical results. The total dosage ranged between 4500 and 7000 roentgen units. Where interstitial irradiation of the glands was necessary two planes of radium had to be employed if any of the glands had a diameter of more than 1 cm, these planes were 2 cm apart. Important details in the after treatment were the avoidance of hot baths and ointments. For the desquamation stage gentian violet was the best application. Moist desquamation was treated with 0.5 per cent silver nitrate solution. Necrosis and residual carcinomatous areas called for excision.

#### Results of Treatment

The cases treated fell into five stages, to stage I belonged the operable primary growths, to stage II the operable primary growths with mobile glands, to stage III the operable cases, to stage IV the cases of recurrence after treatment, and to stage V the hopeless cases. In 1935 nine cases were treated, the three patients with stage I growths were still alive and free from disease, the other six patients died. In 1936 fourteen patients were treated, four cases belonged to stage I and were alive and free from recurrence, two of four stage II cases, the one stage III case and one of the stage IV cases were alive. In discussing the choice between radium and surgery Dr Ellis pointed out that both

methods had their successes and failures. Radium had the advantage over surgery in the absence of shock and of the mortality, minimal damage to the urethra and of wider application to advanced cases. Operation avoided necrosis, there was possibly less subsequent discomfort, precancerous tissues were removed, and there was the possibility of removing affected iliac glands.

D. J. F. STACEY (Sheffield) referred to a paper which he had previously read before the society condemning the use of radium in the cases in view of the seemingly inevitable radium necrosis which had always called for secondary excision of the vulva. Since the introduction of Dr Ellis's technique his views had changed. He had no doubt but that in certain cases radium therapy was now the method of election. The paper was also discussed by Professor W. GOUGH and Mr PERCY MALPAS (Liverpool).

#### Pregnancy and Labour after Repair of Prolapse

Mr BRYAN WILLIAMS (Liverpool) read a paper on pregnancy and labour following operations for prolapse. His attention had been drawn to the problem by the occurrence of a case of severe and almost total dyspareunia due to cervical stenosis following such an operation. He had since seen seventy-two cases of pregnancy following this type of operation, in sixty-two of these all details could be obtained. Five patients had had a ventrofixation performed, no adverse effects were noted in subsequent pregnancies. Thirty-seven patients had had a vaginal repair combined with amputation of the cervix. The operations had been performed by fourteen different surgeons. These patients had a total of forty-nine pregnancies after operation. These figures were too small to decide the question as to whether amputation of the cervix lowered fertility, but they did allow the conclusion to be drawn that the operation was by no means a sterilizing procedure as some authors had claimed. In one case fertility appeared to be increased after the operation. Of the forty-nine pregnancies no less than twenty-eight or 68 per cent ended in abortion or premature labour. Comparison of this figure with the results of pregnancies following vaginal repair in which the cervix had not been touched showed that the factor responsible for the premature termination of pregnancy was the amputation of the cervix. In this latter group of pregnancies following simple colporrhaphy, only two ended in abortion. Twelve of the patients had had perineorrhaphy alone performed, eighteen pregnancies occurred after this operation and sixteen of these went to term. In eleven instances instrumental delivery proved necessary, and fresh lacerations occurred. Taking all the patients in the series in whom the perineum had been repaired, only 29 per cent had a normal delivery without a fresh laceration.

Could anything be done to improve these results? In the speaker's opinion the solution would appear to lie in the avoidance as far as possible of extensive cervical repairs in women of child-bearing age and the increased use of episiotomy early in the second stage in cases in which a previous plastic vaginal operation had been performed. Episiotomy had to be done early if the maximum advantage was to be derived from its use and primary healing ensured. Episiotomy was essential in all cases in which a complete perineal tear had been previously repaired.

#### MEDICAL EDUCATION IN THE EAST

At the annual meeting of the Manchester Medical Society held on May 4, after the annual reports had been read and officers and committee elected, Sir RICHARD NEEDHAM delivered an address on "Observations on Medical Education in India, Ceylon, Singapore and Hong Kong."

He said that the benefits of Western or scientific medicine had been extended throughout India and the Crown

Colonies in the East Yet large tracts and millions of inhabitants were dependent on the aid and comfort provided by native practitioners of the ancient systems of indigenous medicine From an account of the early development of scientific medical education—first of an elementary type and later of an advanced type—and the emergence of two grades of practitioners, licentiates and graduates, he wondered whether the time had come to adopt only one—the advanced or graduate type With the increase in medical schools (elementary) and colleges (graduate) the congregation of both grades of practitioners in the towns had made competition unbearable, with important effects on medical ethics The whole position should be reviewed by the recently established Medical Council of India The curriculum provided by the Indian medical colleges was sketched stage by stage in general terms It had been organized from the first and planned in a general way on lines as adopted in Great Britain, and had so continued The opportunities for clinical studies and research were unsurpassed The teaching institutions, whether schools, colleges, or hospitals, were initiated by the Governments, and in one way or other their continuation and maintenance are provided by Government—the object being to provide an agency to extend scientific medical aid to the peoples This was equally so in India, Burma, Ceylon, Singapore, and Hong Kong The cost of providing first-grade medical education, involving an ever-increasing budgetary grant from official sources of Government, had meant delay and hampered progress Except in India there was only the graduate grade of education, since the elementary grade had been abolished In conclusion Sir Richard Needham discussed the effects of Government control, social customs, local conditions, climate, distances between colleges, and consequent tendency to isolation

#### FORTY YEARS' PROGRESS IN MEDICINE

At a meeting of the Mid-Staffordshire Medical Society on May 3 Professor F S LANGMEAD of St Mary's Hospital gave an address on "Retrospect and Prospect in Medicine"

Professor Langmead dealt with the progress of medicine during the last forty years—the period covered by his experience It was fallacious to estimate progress by some outstanding discovery, no matter how important A truer conception could be formed by considering the steady increase of knowledge over the whole field He viewed many of the more important extensions of medical knowledge and procedure, and emphasized particularly the contrast between radiology and biochemistry forty years ago and to-day In his opinion the advance in radiology had contributed more to better diagnosis and treatment than had any other factor Its importance was rivalled only by that of biochemistry He looked to biochemistry for an understanding of the soil as distinct from the seed of disease, or immunity, and of diathesis, though those were fields to be cultivated by tools not yet forged

#### The Growth of Specialism

Professor Langmead then referred to the necessary growth of specialism which had taken place The body of medicine being sliced vertically according to diseases and transversely according to ages had become a sort of minced meat of which each specialist digested his own small piece The advantage of specialization was obvious but there were attendant drawbacks By intensive study of one small part more and more truths emerged from a context growing ever dimmer The disadvantages could be sensibly reduced if specialization were only permitted after a reasonable experience of general medicine and surgery had been acquired after qualification He thought that the faculty of absorbing all that could be

learnt through the eyes, the fingers, and the ears had weakened by desuetude in the last forty years, and that if cut off from modern methods the young physician would be less accurate in the estimation of a case than were his teachers Science had separated more widely from art and the classics "Little Latin and less Greek" had often become "No Latin and no Greek and very little English as well"

The immense progress made in medicine and the growth of the many special subjects had laid a heavy burden on the student, who was able to give less study to individual cases in the wards than was customary forty years ago So many courses of instruction were required by the General Medical Council and the examining bodies that there was little time to think or to correlate To ease the burden there were but two alternatives a longer period of study, or curtailment of the subjects of less immediate value The latter would be a serious step to take Important committees had recently spent much time over the problem and had ruled out extension of the curriculum as being impracticable Being left with the problem of a quart which had to be fitted into a pint pot, they had added a few ounces to the volume, while the pot was a pint still He concluded by indicating that a revolution had quietly occurred in the status of the profession in relation to the State It appeared that in the near future four out of every five of the population would come under a scheme of State medicine Two things he held to be essential if medical progress were to continue unchecked individual liberty for the doctor, unhampered by unnecessary reports and explanations and with freedom to do his best for the patient in his own way, even though that might be unorthodox, and retention of the great teaching hospitals, with their high tradition of service, experiment, and instruction, even if they should need the financial assistance of the State

## Local News

### IRELAND

#### Air Raid Precautions in Northern Ireland

For some months past the St John Ambulance Association has been responsible for educating and instructing the public in the necessity for and the means of attending to casualties occurring as the result of air raids The Ministry of Home Affairs has now appointed Colonel T C C Leslie, AMS, to be medical instructor, and instruction of doctors, dentists, and veterinary surgeons will now proceed during the coming months The large shipbuilding yards, aircraft factory, and numerous linen factories, as well as the other industries, of Belfast would provide an objective for hostile aircraft in the event of war, and the authorities are well aware of their responsibility in the matter The air raid precautions officer of the Ministry will co operate with the instructor and the branches of the medical profession in keeping abreast of the developments in other centres, and be in a position to advise local authorities as well as industrial establishments as to the best means of protection

#### Royal Maternity Hospital, Belfast

The recent annual meeting of the Royal Maternity Hospital, Belfast, was the occasion for a record of a successful year's work The number of patients has increased both within the hospital and in the hospital districts Lady Clark took the opportunity of congratulating the hospital upon its valuable services to the community of Northern Ireland and appealed for financial support to meet the annual deficit Reference was made

to the new department for paying patients which is to be named Johnstone House is a tribute to the long connexion with and valuable services rendered by Sir Robert Johnstone to the hospital and which it is expected will be in operation within a few weeks. It will cater for those members of the community who find difficulty in obtaining the type of accommodation which their means allow. The unit contains fifteen beds with an attached nursery for babies and a well equipped theatre and delivery suite. Cubicles and single rooms are provided.

#### Ulster Hospital for Women and Children

The annual report of the Ulster Hospital records a year of increased activity. The number of beds now available is 116. The total expenditure for the year amounted to over £8,000 to meet which some £600 from a number of donations was added to the ordinary income from investments and subscriptions. That this hospital in the east of Belfast fills a very definite place in the lives of the people of the district is clear from the numbers attending the hospital. In the children's department there were 9,697 new cases and 42,240 attendances; in the gynaecological department there were 2,549 new patients and in the obstetric unit 116 cases.

## ENGLAND AND WALES

#### Education in the Open Air

At the opening of the Havling Island Open Air School under the Tottenham Local Education Authority Mr. Kenneth Lindsay, Parliamentary Secretary to the Board of Education, said that it was now just over thirty years since the movement towards the open air treatment of delicate children which originated on the Continent resulted in the establishment in this country of the first open air schools at Plumstead, Hailuay, Bradford, Norwich and Sheffield. The number of these schools had now increased from seven in 1910 to 133 to-day with accommodation for over 16,000 children and 33,200 children passed through these schools last year. The open air school was not merely a school in the open air, it comprised a way of life and a system both of educational and medical supervision characterized by fresh air and sunlight, a proper and sufficient diet, adequate rest, a hygienic regimen from regular bathing, to participation in formal physical training, medical treatment, individual attention and special educational methods. More and more children in our complex modern civilization were finding it difficult to get the proper amount of sleep for their age under restful conditions and it was a healthy rule in open air schools that one and a half to two hours in the middle of the day shall be spent by the children in the horizontal position. The children attending open air schools, said Mr. Lindsay, are very carefully selected but we should be careful not to look upon the principles of open air education as applicable for that reason only to a special class of children who are suffering from anaemia, debility or other conditions of sub-normal health. The ideals practised in the open air school should be spread among the whole of the school community.

#### Medical Students Conference

The Medical Students Committee of the National Union of Students in co-operation with the Irish Students Association and the Scottish N.U.S. has arranged the second annual conference of representatives of medical student societies to be held in London from July 12 to 15. Accommodation (bed and breakfast) will be provided for men delegates at the University of London Hostel Connaught Hall, Torrington Square, W.C.1 and for women

delegates at Courtauld House, Byng Place, W.C.1. The general subject for discussion is "The Training of the Doctor." The conference will open with a dinner on the evening of Tuesday, July 12, at Pinolis Restaurant, Wardour Street, at which the chief guest will be Lord Horde. The speaker at the first meeting on July 13 will be Sir Henry Brackenbury, chairman of the Committee on Medical Education of the B.M.A. In the afternoon Professor C. A. Lovatt Evans will speak on "The Relation of Pre-clinical Subjects to the Medical Curriculum as a Whole." The speaker at the morning session on July 14 will be Mr. Eric Pearce Gould and in the afternoon Professor W. W. Jameson will open a discussion on "The Teaching of Preventive Medicine." The whole of Friday, July 15, is set apart for clinical visits to the Middlesex Hospital, University College Hospital and the Royal Free Hospital. The conference fee which includes the cost of bed and breakfast for the nights July 12 to 14 inclusive and of the opening dinner is 30s a head. The fee for London delegates not requiring accommodation is 10s. Every student society may appoint 10 delegates to the conference and it is entitled to send further members as observers. The discussions under the general title of "The Training of the Doctor" will be based upon the reports on medical education issued by committees of the British Medical Association and the General Medical Council. In order that the discussion at the London conference may be well informed, medical societies are asked to buy copies of these reports and to get them examined by a committee or discuss on group so that the representatives may be in a position to put forward carefully considered views.

Medical societies in Czechoslovakia, Hungary and Yugoslavia offer facilities for the exchange of medical students during the summer months. Students interested in these exchange offers should apply as soon as possible to the Secretary, Medical Students Committee, 3 Endsleigh Street, London, W.C.1.

#### L.C.C. Nurses' Introduction of 96-Hour Fortnight

The evidence recently submitted by the British Medical Association to the Interdepartmental Committee on Nursing Services (*Supplement* May 14, p. 301) recommends *inter alia* a maximum working period of 96 hours a fortnight exclusive of meals taken out of the ward but inclusive of meals taken in the ward and the time devoted to lectures. On almost the same day on which this evidence was published the London County Council adopted proposals for the reduction of hours of duty of its nursing staff from 54 a week to 96 a fortnight at all hospitals. The hours of duty worked by nurses in the hospitals taken over by the Council in 1930 from the Metropolitan Asylums Board and the boards of guardians have varied considerably. In the Board's hospitals the hours of duty were 25, 56 and 58 for day and 60 for night. A 96-hour fortnight for nursing staff in the mental services was introduced in 1919 and the Hospitals and Medical Services Committee after reviewing the situation has come to the conclusion that the time has arrived when all the general and special hospitals should have the same duty system. It will enable the split-duty system which has been the cause of much dissatisfaction among nurses to be abolished and from every standpoint alike—the welfare of the nurses, the improvement of the standard of nursing and the care of the patients—it is considered that a 96-hour fortnight and a straight shift system will be a highly progressive step. The alteration will necessitate an increase of about 1,000 units of nursing staff. It is also proposed to introduce several other changes of a minor character. The best arrangement for night duty is considered to be a 10½-hour shift on nine nights in fourteen. The time allowed each night for meals will be one hour and twenty minutes and the arrangement will obviate the necessity for shifts changing over during the night or very early morning hours. It is proposed as far

as possible to eliminate lectures for staff while on night duty, but where this is unavoidable a special morning course will be provided for the staff concerned. The 96-hour fortnight system will apply to the fever hospitals, though it is feared that during epidemic periods it may be impossible to provide for a sufficient number of staff to enable the adequate nursing of the patients to be carried out on that basis, and it may be necessary temporarily to revert to the 54-hour week. Certain additional facilities and amenities are to be provided for the resident female nursing staff. Facilities have already been granted to all nurses other than probationers to have leave of absence from the hospital after duty every evening until midnight without having to obtain previous permission. Extension beyond midnight is not, as hitherto, to be the subject of a request to the matron, but to be regarded as normal freedom for trained staff. Certain facilities as to leave are also to be granted to probationer nurses. Members of the nursing staff are to be allowed to use gymnastic apparatus in the massage department in the evenings after the department is closed to patients. Rooms for games, theatricals, and the like are to be provided, nurses are to be allowed to have breakfast or supper in bed on days off or evenings off, residential accommodation at country or seaside hospitals for staff requiring convalescent treatment is to be extended. Finally, weekly periodicals are to be supplied to the staff common rooms. The change in duty periods will be made as from July 1, but in view of the fact that 1,000 nurses will have to be recruited it is evident that an intensive recruiting campaign recommending nursing under modern conditions as a career for young girls will have to be undertaken if the scheme is to be fully effective within a reasonable time.

## INDIA

### Association of Surgeons in India

The meeting to inaugurate the Association of Surgeons in India, to which previous reference was made in these columns on March 26 (p. 697), is to be held in Bombay in October. The surgeons of Bombay have formed a reception committee and are making the local arrangements. It is now announced that Dr. M. D. D. Gilder, the Minister for Public Health, Bombay, will preside and will deliver the inaugural address. Discussions will be held on ileocaecal tuberculosis and carcinoma of the tongue. It is hoped that papers on other subjects will also be contributed by surgeons from other parts of India, and that the new association will find itself in a position to publish a periodical devoted to surgical subjects. Further information may be obtained from the organizing secretary of the Association of Surgeons in India, "Binfield," Kilpauk, Madras.

### Infantile Mortality in Madras

The Director of Public Health, Madras, in his report for 1936 states that although there has been an improvement in the registration of vital statistics, the fact remains that unless and until qualified medical agencies are established in the rural areas and the villagers are made to realize that the recognition of their own existence and that of their families is linked up with prompt reporting of all vital occurrences, a high degree of accuracy of returns cannot be expected. Financial considerations may not permit the employment of such agencies throughout the Presidency, but the utilization of the services of the existing subsidized medical practitioners of whom there are over 400 would undoubtedly help very much in obtaining more accurate returns. It is not at present obligatory for these medical practitioners to take up public health work yet apart from being the very foundation of all

public health activities, such accurate vital records have a very high civic and legal value. Lieutenant Colonel Ganapathy further states that no person should have a legal existence unless there is a birth certificate granted by the proper authority, containing all necessary details, while no dead body should be subjected to cremation or burial until a proper death certificate has been obtained. Deaths among children under 1 year during 1936 numbered 272,393, the infantile mortality rate decreased from 178.47 per 1,000 in 1935 to 164.04 in 1936. More than 50 per cent of the infants died within one month of birth. The death rates for all age groups in rural areas are lower than those for the urban areas, except in respect of deaths during the first month of life. The neo-natal mortality rate is influenced chiefly by unfavourable maternal conditions and the various adverse factors which come into play during the confinement and immediately afterwards. It should be expected, therefore, that in rural areas with hardly any maternity service the neo-natal mortality rate will be higher than in urban areas. In spite of this higher neo-natal mortality rate the total infant mortality rate in rural districts is distinctly lower than that for urban areas. Unfavourable environmental conditions such as congestion, overcrowding, poor sanitation, and defective drainage generally obtaining in the towns are certainly inimical to infant life. Except during the child-bearing period the mortality rates among females in Madras are lower than are those for males. The raised death rate among women during the child-bearing age indicates the necessity for having a well-organized maternity service. In both urban and rural districts there is a high death rate in infancy, but it falls rapidly, reaching a minimum in the age group 10 to 15 years. Colonel Ganapathy adds that the high birth rate and vital index in Madras indicate the rapid growth of the population.

### The Anti-tuberculosis Fund

Reference was made in this column on December 11 last to the launching of a fund to combat tuberculosis in India, to be called the King-Emperor's Fund. This organization will concern itself with the prevention and treatment of tuberculosis throughout India, where deaths from that disease are estimated to number some half a million every year. Its aim is to encourage and expand the work of existing anti-tuberculosis organizations, and 95 per cent of the money raised will be spent in the areas which contribute to the fund. Committees have been formed in the Provinces and many States in India for the collection of donations to the fund. In England the High Commissioner, Sir Feroz Khan Noon, has issued an appeal for help, and a regional committee has been set up in London to bring the work of the fund to the notice of India's sympathizers and well-wishers in this country. "Their Majesties have shown a personal interest in this noble project. Its object is to establish and finance an All-India organization for the prevention and treatment of this silent enemy of my countrymen."

### A Diploma in Obstetrics and Gynaecology

The Council of the College of Physicians and Surgeons of Bombay, at its meeting held in January, 1937, decided to institute an examination for a diploma in obstetrics and gynaecology, and appointed a committee to draw up regulations and a syllabus of study for that examination. This committee submitted its report to the meeting of the Council on March 11, 1938. The report was approved and adopted, and it was resolved to hold the first examination for the Bombay Diploma in Obstetrics and Gynaecology (D.G.O.) in August 1939. It will be open to all practitioners registered with the Bombay Medical Council. Copies of the regulations may be obtained from the secretary of the College, 19, New Market, Bombay.

## Thyrotoxicosis

SIR—My friend Mr Peter McEwan puts us all in his debt for the brilliant statistical and clinical study of thyrotoxicosis published in the *Journal* of May 14 (p 1037). He—no doubt with malice prepense—courts controversy on many of the issues he raises but I have too much regard for your spice to do more than touch on two matters which I think are of some importance.

Mr McEwan quotes me (p 1040) as attributing the increase in the death rate from thyrotoxicosis in recent years to iodine medication but he does not make it as clear as I should have liked that the increased mortality is due as I hold not to any great tendency for iodine to initiate toxic changes in simple goitre but to persistence in treating established thyrotoxicosis by iodine in spite of its failure to cure or even permanently to ameliorate the condition. The pathetic faith in iodine therapy is not by any means always inculcated by the physician or the patient's private practitioner since it is widely held among the laity that iodine cures goitre. Unfortunately iodine is not on the official schedule of poisons though I believe it has done more harm than some which appear on that list and can be purchased in any quantity by anybody. Mr McEwan also refers to that most controversial problem thyrotoxicosis in the absence of an enlarged thyroid gland. I am sure he will forgive me for pointing out that the photographs he publishes prove nothing since many goitres which are invisible in the very best photographs are nevertheless quite definitely palpable. I do not believe that thyrotoxicosis can exist with a normal thyroid gland—that is normal both in size and structure. Mr McEwan states that in the case quoted the gland was "anything reduced in size yet he omits to tell us anything of its structure—an omission which seems odd in view of its critical importance. He says that in such cases the diagnosis must be clearly established but that is the crux of the whole matter and I should be glad to hear how it is done in Bradford. In London I am still often in grave doubt as to whether a diagnosis of thyrotoxicosis is or is not substantiable. I am often urged to operate on the type of patient who has tremor nervousness tachycardia etc but without any palpable goitre. On a few occasions when the basal metabolic rate and cardiac investigations appeared to confirm the diagnosis of masked hyperthyroidism I have in fact exposed the gland only to find that it had a normal appearance and consistence. In these cases I have excised a portion of gland tissue for investigation and the pathologist's report has been in all "normal thyroid tissue"—I am etc.

London W 1 May 16

Cecil A JOLL.

## Psoriasis

SIR—I read with interest Dr John T Ingram's article on the present position as regards psoriasis (*Journal* April 23 p 881) particularly his remarks on aetiological factors. In the period 1931 to 1934 I made in Glasgow a study of this interesting disease. May I say that Dr Ingram puts the matter aptly when he writes "It is as true to say we do not know the cause of psoriasis as it is to say that we do not know the cause of any other constitutional reaction—for example eczema or dyspepsia. With the exception of Dr Ingram's and Dr Barber's

valuable contributions on pustular psoriasis and acrodermatitis continua vel persians little has appeared in the literature of this country during the past twenty years. It is to the credit of British dermatologists that having had the improved facts to add to our knowledge they have not confused the issue by putting forward hypotheses based on flimsy foundations. I wonder however if psoriasis is as common a disease as would appear from statistics compiled in the skin departments of our hospitals. Radcliffe Crocker (1905) gave the incidence as compared with all skin diseases as 7 per cent in his hospital patients. Abraham for the period 1900 to 1904 found an incidence of 7.4 per cent. Both these figures are for London. In Glasgow in 1894 McCall Anderson found the percentage to be 8.6 in his hospital patients. Dr J Ferguson Smith has kindly allowed me to give the results arrived at for the ten years from 1924 to 1933 in the Glasgow Royal Infirmary. Out of a total of 39,963 patients attending for the first time at the out-patient department for diseases of the skin 1,796 (4.5 per cent) were diagnosed as cases of psoriasis. I cannot from the available information explain the discrepancy between McCall Anderson's figure and that now given for 1924 to 1933.

Nothing is known of the prevalence of psoriasis in the population generally. As medical officer to a large bank in Glasgow I examined in 1937 over 100 new employees or individuals seeking employment. Most of the persons were girls between 14 and 21 years of age—at which period psoriasis is very apt to appear for the first time. In no case did I see the typical lesions of psoriasis. It must be admitted that only when varicose veins were present or there was evidence of rheumatism or rickets in other parts were the naked legs and knees examined. In every case however the scalp the extensor surfaces of the elbows and the chest and back were seen. The only election of these cases was that the lady supervisor before medical examination rejected applicants who were obviously not cleanly. There is however no evidence that psoriasis is more prevalent among the unwashed. It may be argued that persons with a chronic skin condition would be unlikely to apply for a job in a bakery especially if they knew the case was a medical examination. I do not think this is so as I seldom visit the factory without referring to their own doctor one or more cases of acne vulgaris and or seborrhoeic dermatitis generally visible when the patient is fully clothed and sometimes extensive. In my opinion the predominance of female employees is not a factor explaining the absence of psoriasis as in 1924 to 1933 in the Royal Infirmary the sex incidence was 59.4 per cent females and 40.6 per cent males. The female psoriatic is more likely than the male to apply for treatment of an eruption which from the patient's point of view may make inadvisable the wearing of short sleeved garments.

The number of these bakery employees is at present too small to warrant any conclusions being drawn from their investigation. It might be of interest, say in seven years time to put on record the incidence of psoriasis in these young people as all employees under 21 years of age are examined by me annually. I have to thank the directors of Messrs Bilsland Brothers Ltd for permission to make these observations and Miss Duncan the supervisor for her interest in the medical welfare work of the bakery—I am etc.

Glasgow W.2, May 10

W S W GUTHRIE.

## The Planning of Maternity Hospitals

SIR—Like your correspondent Dr Henry H MacWilliam (May 14 p 1068) I was much surprised to read in the *Journal* of April 30 a criticism of the recommendation in the final report of the Departmental Committee on Maternal Mortality and Morbidity that new

maternity accommodation should, when practicable be associated with general hospitals and your statement that "it is now, however, generally accepted that this recommendation is not in accordance with the lessons of experience"

As a member of that committee and therefore jointly responsible for the recommendation in question, I wish to state that further experience, since the final report of the committee was issued in 1932, has only served to confirm the opinion I then held and which was in full accord with that expressed in the report. That opinion is based upon experience as a member of the staff of two maternity hospitals, one attached to a general hospital and the other not. My reasons for preferring the former are clearly set out in Dr MacWilliam's letter, and need not be mentioned again here.

To my mind there is no comparison between the facilities available in the two kinds of institution for diagnosis and treatment of the difficult or obscure cases with medical or surgical complications that are constantly turning up in an obstetric hospital. This is, of course, because one can at all times obtain the *early and continued* co-operation of the physicians, surgeons, clinical pathologists, radiologists, physical therapists, etc., who are colleagues on the staff of a general hospital. In an isolated maternity hospital these facilities simply cannot be supplied, and in consequence the interests of the patients must suffer—I am, etc.,

### Treatment of Placenta Praevia

SIR—Several interesting points arise out of Dr H G Oliver's account of his case of placenta praevia (*Journal*, May 14 p 1071). It is unusual that in such a case the head should be engaged twenty-eight days before term, and still more so that after labour had started and the membranes had ruptured a steady loss of blood should occur although the head was engaged in the pelvis. I find it difficult to understand, as, if the head was engaged, surely it was compressing the placental site of a praevia placenta. Cases of placenta praevia of the lateral or marginal type in which the patient is in labour rarely require any treatment beyond puncture of the membranes, and when the bag has already ruptured one would regard the situation as ideal without further treatment.

It would be a great pity if the advocacy of manual dilatation of the cervix followed by forceps extraction for such a case were left unchallenged as this treatment is frequently fatal. I know of three cases seen by me where it proved so. As has often been pointed out, manipulations involving the cervix which is unusually soft and vascular owing to the adjacent placenta praevia, are very apt to be followed by cervical laceration and haemorrhage, even when gently carried out. Dr Oliver, therefore, who obtained no cervical damage was not only skilful but also fortunate. In my view, when placenta praevia must be treated in the home the feasible lines of treatment to control haemorrhage are puncture of the membranes, the use of Willett's forceps and version. In this case, if I understand aright my reaction to the haemorrhage which occurred after the membranes had ruptured would have been to apply Willett's forceps.

I think that in many cases of placenta praevia it is possible to be reasonably certain of the diagnosis without vaginal examination, and so avoid this risk before carrying out Caesarean section—I am, etc.,

### "Gonococcus Antitoxin" for Gonorrhoea

SIR—With reference to Dr T Anwyl Davies's letter in the *Journal* of May 14 (p 1069) the main point at issue is how the extraordinary discrepancy between his results and ours is to be explained. Three things naturally suggest themselves: (1) that there was some difference in the "antitoxin" used by him and that used by us in respect of composition or of dosage; (2) that different criteria of observation were used in the two series; and (3) that the adjuvant treatment used by Dr Anwyl-Davies is responsible for the good results he claims even though in his first series of cases protosil or some allied substance was not used.

In our series treated by "antitoxin" alone, followed by urethral irrigations, it was shown beyond any doubt that this preparation was not only ineffective but positively harmful. Assuming that the "antitoxin" used by Dr Anwyl-Davies was identical with that used by us, and that the criteria of observation were similarly adequate in both instances, then the explanation for the divergent results must be attributed to the adjuvant treatment given by Dr Anwyl-Davies. The question then arises: Are the results obtained by "antitoxin plus adjuvant treatment in any way better than those obtained by the adjuvant treatment alone?" Unfortunately, the details of the adjuvant treatment used by Dr Anwyl Davies have not yet been stated. We have not yet availed ourselves of the invitation to examine the original case-records of Dr Anwyl-Davies's patients because we naturally expected that he would, in response to our inquiry, have given us the information we asked through the medium of your columns. It is rather difficult to understand why Dr Anwyl-Davies should have thought it incumbent upon us, before publishing our article, either to ask for his observations or to inform him of our experiences with the "antitoxin," even if it had been a "new product still in the early stages of investigation." This is hardly a correct description, since when our work was carried out this preparation was available for purchase in the open drug market, and was extensively advertised in the medical press (*vide Journal* July 10 1937, p 28, and also a full back page advertisement in Parke, Davis and Co's *Therapeutic Notes* September 1937). The material with which we worked at two out of three clinics was purchased in the ordinary way and was not provided by the manufacturers for research or clinical investigation purposes—we are, etc.,

### Insulin for Schizophrenia

SIR—It is interesting to note that much the same arguments which fifteen years ago were raised against an important advance in psychiatry—the malarial treatment of general paralysis of the insane—are now being raised by Dr B H Shaw (*Journal* May 7, p 1026) against another advance, incidentally originating from the same mental hospital—namely the insulin treatment of schizophrenia. It is all to the good that those who have seen many new treatments come and go should reserve their judgment of this comparatively new one. It is sad, however, that so distinguished a psychiatrist should be under the misapprehension that insulin therapy is a

treatment a conception dropped some time ago by those familiar with the therapy in question. Dr Isabel Wilson in her official report published in 1936 doubted whether the insulin effect was properly to be classed with shock at all and suggested the more fitting title of high dosage insulin treatment. Since then it has generally been recognized that the element of shock does not predominate in insulin treatment and that hypoglycaemia rather than shock is the therapeutic agent.

As to the extremely dangerous nature of such a procedure closely verging on dissolution it is illuminating to watch the patients who have undergone such treatment in the morning playing tennis in the afternoon as a matter of routine. The fact that by now close on ten thousand patients have had insulin treatment indicates that Great Britain does not stand alone in the most regrettable tendency towards propagandism in relation to the treatment of mental disorder from the importation of psychoanalysis to the latest exotic. Is Dr Shaw right in describing insulin therapy as the latest exotic? Does not that distinction belong to the cardiazol therapy of schizophrenia which is now being widely used in this country?—I am, etc

H PULLAR STRECKER

### Technique of Anaesthesia

SIR—In the *Journal* of February 5 (p 283) Dr Michael Cohen describes a case of tumour of the vocal cord following nasal endotracheal anaesthesia. In the report of this case there appears not the slightest indication for the adoption of this objectionable method of administering an anaesthetic. If an endotracheal anaesthesia be required there is only one reasonable method of introducing the anaesthetic tube, and that is by direct vision through a sterilizable laryngoscope. The passage of a tube through the nose which may be more or less obstructed and which is probably the site of growth of pathogenic organisms into the larynx or trachea which is liable to be abraded thereby is unjustifiable save in very exceptional circumstances. If it is desirable for the convenience of the operator not to have the tubes actually in the mouth then the upper end should be drawn out through the nose from the nasopharynx.

With reference to Dr G. R. Osborn's article 'Why Post anaesthetic Pulmonary Complications?' the two principal considerations in the administration of a general anaesthetic (apart from dosage) are (a) the maintenance of a clear airway and (b) the prevention of the entrance of foreign matter into the larynx, trachea, and lungs. This is of equal importance during the stage of recovery from the anaesthetic. Three cases stand out in my memory.

(1) A married woman about 27 years of age underwent a laparotomy for some non-infectious pelvic condition under open ether anaesthesia. About half way through the operation the patient whose breathing had been very wet became asphyxiated. I was requested to help the anaesthetist. The patient's tongue was drawn out and the pharynx was mopped out. Her colour improved and the operation was duly completed. Within a few days the patient developed some form of bronchopneumonia from which she took six to eight weeks to recover. This could not have been caused by septic emboli from the field of operation but was undoubtedly due to the anaesthetic.

(2) A middle-aged man of plethoric type had a radical operation upon both maxillary antra which were extensively diseased under intratracheal anaesthesia. Nothing untoward happened during the operation but about fifteen minutes later

I was called urgently to see him. He was a ghastly colour and his first glance appeared to be dead. His skin was very moist and he was making very feeble attempts at respiration. The patient was on his back and the tongue had doubled upon it. He had choked him. He recovered but had a subacute lung condition which lasted some months. This was not a septic aspiration pneumonia which one might have expected but some damage done by the anaesthetic was combined with the effects of the subsequent asphyxia.

(3) My knowledge of this case is obtained from reports of a coroner's inquiry published in the daily press. A young woman was submitted to a simple curettage under general anaesthesia. After being returned to the ward she vomited while still unconscious and was fatally asphyxiated by the vomitus.

Case 1 emphasizes the necessity for the maintenance of a clear airway during the administration of an anaesthetic. Cases 2 and 3 demonstrate the necessity for a clear airway during the recovery period. All these cases indicate the need for the use of some traction apparatus on the tongue during both the administration of the anaesthetic and the recovery period until the patient is fully conscious. It is common practice after the administration of an anaesthetic for the patient to be placed flat on his back with the head turned to the side. This is objectionable as it distorts the air passages and tends to interfere with respiration. Cases 2 and 3 indicate that the patient should be in a lateral posture the upper knee slightly flexed and the head on a low pillow (to prevent accumulations in the nasopharynx) with the face turned slightly down and some means of traction applied to the tongue. In this position provided also that the patient be under proper observation it is highly improbable that aspiration of vomitus or interference with respiration will occur. Apart from orthopaedic cases there must be very few in which this posture cannot be used. In this position any vomiting will place less strain on an operation wound than in the unnatural position of lying on his back with the head twisted to one side and the vomitus and secretions will be carried away from the larynx by gravity aided by the expulsive efforts of the vomiting. It is remarkable how often these simple and elementary yet important precautions are neglected—I am, etc.

ERNEST CULPIN

Brisbane, Queensland, March 10

M.B. CH.M. FRACS

### Divinyl Ether Anaesthesia

SIR—I would like to support Dr E. B. Grogono's suggestion (*Journal* May 14 p 1068) that more attention should be given to divinyl ether (May and Baker's vinesthene) an anaesthetic which is particularly suitable for use by the general practitioner anaesthetist because of the ease with which it can be administered, its safety and the absence of after-effects. It is important for the general practitioner that he shall not be required to purchase and to carry about expensive and complicated apparatus and the simplicity with which vinesthene can be used is greatly in its favour. To my mind the greatest advantage of vinesthene is the ease with which anaesthesia is induced. There is no struggling coughing, vomiting or any other of those undesirable features so commonly associated with induction by ether and in addition to this ease of induction its use appears to be safe.

I have found it particularly valuable in just those cases in which one would expect trouble with an ether induction as for example in the robust middle-aged or elderly man coming to hospital as an accident case or a surgical emergency. Gas and oxygen anaesthesia is hardly satisfactory in either of these

tion presents difficulties and chloroform is not very safe, but with the use of vinesthene these difficulties disappear. In order to avoid any special apparatus I have made use of apparatus already at hand. For the robust individual such as I have described I break three of the glass capsules (9 ccm) of vinesthene and empty them into a Clover's inhaler. The patient is told to take a deep inspiration, the mask of Clover's inhaler is placed over his face and he breathes out into the bag. The barrel of the apparatus is then turned fairly quickly to 2 and in about twenty breaths the patient is anaesthetized with quite remarkable ease. The anaesthetic can be continued for about ten to twelve minutes by allowing one breath of air in every four. Adequate relaxation is obtained, and in the majority of cases there is no bad after effect, so that the patient can go home.

Vinesthene is remarkably useful for the case in which gas and oxygen would not quite suffice—for example the patient (so often an ill and elderly man) admitted with acute retention of urine on whom it is proposed to perform suprapubic cystotomy. For such a case I make use of Clover's inhaler, which is joined in circuit to the ordinary Boyle's gas-oxygen-ether machine. In this case only two ampoules of vinesthene are emptied into the inhaler. The gas and oxygen are then turned on, the facepiece applied, and the barrel turned fairly quickly to 2. In about fifteen or twenty breaths the patient is anaesthetized, and the operation can proceed. A vinesthene-gas oxygen anaesthetic is then maintained with adequate relaxation without the addition of ether.

It is however particularly for the operation of Caesarean section that vinesthene is so very valuable. In these cases I place the vinesthene in the chloroform bottle (having first emptied out the chloroform) of a Boyle's apparatus. If the operation is likely to be short I empty 25 ccm of vinesthene into the bottle; if long 50 ccm. I do not attempt the induction until the surgeon is ready to operate, because vinesthene is very volatile and is quickly used up. The induction is rapid and the surgeon is not kept waiting. I turn on the nitrous oxide-oxygen with the Boyle's machine (in the sight feed-bottle oxygen is bubbling through two holes the nitrous oxide through five holes) and blow the mixed gases over the vinesthene. I find that by this means a light but adequate anaesthesia can be maintained. In some cases I have found it desirable to add a little ether just before the surgeon stitches up the peritoneum but it is not necessary in every case, and even when it is necessary I find that all that is required is to turn on the ether bottle for twenty breaths. Vinesthene appears to have little or no effect on the uterine muscle, so at the end of the operation the uterus will rapidly contract, and there is less risk of haemorrhage.

Vinesthene is most suitable for very ill patients, the neglected cases of intestinal obstruction or those cases where an anaesthetic is required for the treatment of patients gravely injured in some motor accident. With this type of emergency surgery premedication is almost out of the question and it is extremely difficult for those who are not very expert anaesthetists to obtain and maintain adequate anaesthesia with nitrous oxide and oxygen but the addition of vinesthene to the gases relieves the anaesthetist of most of his difficulties and the surgeon of many of his anxieties. In these cases I usually place vinesthene in the chloroform bottle of the Boyle's machine, as already described but where the Boyle's apparatus is not available I see no reason why vinesthene should not be used in a Shipway or some similar apparatus. Vinesthene is a non-irritating anaesthetic and it should have a place in chest surgery although my own experience of its use in this particular branch of surgery has been confined to the opening and draining of empyemata.

I have been using vinesthene for about a year as a general practitioner anaesthetist, and as such, of course, my experience is limited but I have noticed with regret that there has been little mention of this anaesthetic in the medical press. I venture to hope that some of our expert anaesthetists will carry out further work on this extremely interesting and valuable agent—I am, etc.,

New Barnet, May 14

JOHN ELAM

## Origin of Cancer

SIR—Dr Cramer's wide outlook on the problem of cancer makes his paper published in the *Journal* of April 16 (p 829) refreshing reading. A cure for cancer must remain as far off as ever so long as treatment and research are based on the assumption that cancer is a localized disease. The primary lesion can no more be the whole story of cancer than the primary chancre can be the whole history of syphilis. Complete removal or destruction of the chancre, however skilful, can never cure syphilis, and so complete destruction of the primary growth can never cure cancer. Dr Cramer's remarks show the importance of conserving the power of resistance. Unfortunately, deep therapy does the opposite by putting a severe strain on the patient, who is already in a low state. Some survive treatment, many do not.

I know of patients who have been told that the treatment will do no good unless they are burnt. I agree with the late Mr Furnivall when he suggested that patients should be warned of the post-radiation reactions. That the medical profession may form a rough idea as to the present day value of deep x-ray therapy in cancer I suggest that the larger hospitals should publish the composite total of all cancer cases treated by this method, and how many of these are symptom free at the end of a three-year period, a period of five years would possibly be too severe a test—I am, etc.,

London, W 1, May 13

S GILBERT SCOTT

SIR—The suggestion concerning the genesis of malignant growths brought forward by Dr H W Eddison in the *Journal* of May 14 (p 1069) appears to me to be contradicted by facts, both of human physiology and of animal and plant biology. His separation of the surface of the body of man and other land inhabiting organisms into two categories—aerial and aquatic—whereby contact is effected with the two corresponding types of environment however original, is scarcely legitimate. Protoplasm during all the million years of its evolution and differentiation, whether composing the ganglia of a jelly fish or the brain of a human being, has never emancipated itself from the thralldom that cradled its birth—a watery environment, direct contact with the atmosphere spells its death.

This very significant point was stressed in 1903 by two independent observers—A B Macallum and R Quinlan. The latter, in what has been termed the 'Quinlan hypothesis,' likened man to a marine aquarium filled with sea water resembling in salinity the early ocean in which his lowly animal ancestors had their being. As the various forms of living creatures, invertebrate and vertebrate, left the water they took with them, so to speak, this saline fluid, sealed up in their bodies by membranes. In such physiological salt solution each living cell of their descendants' bodies has ever since been immersed. Even the "naked" living matter—such as the plasmodium of the familiar slime mould (*Myxomycetes*) on decaying vegetation, the surface cells of the cornea or of mucous membranes—only makes an apparent contact with the air. It is to live its actual contact must always be with a saline solution. The stomata "guard cells" of leaves, the air-cells of our lungs, etc., are powerless to deal directly with gaseous oxygen for they can only carry on their metabolic processes in and through the mediation of water. At bottom even our respiration is aquatic for the oxygen we draw down as a gas into our lungs is useless until it becomes dissolved in water. Every living cell, whether of the most case hardened xerophilous or

growing from the sun scorched sands of the desert or of the pulpy little book worm *Trochus divinator* that spends the greater part of its mischievous life bowing on the dry as dust leaves of old volumes can only remain actively alive while bathed in a physiological salt solution. All metabolism whether pertaining to the internal contents or the surface area of the living cell takes place in an aquatic medium and there is in strict truth no surface of such a cell that can be regarded—as Dr Eadison suggests—as transitional between the aerial and aquatic state.

In 1896 Sir Archdall Reid maintained that the cancer cell was a reversion to the ever-dividing primordial type of cell a view which as much of this most interesting correspondence in your columns has indicated is at long last coming into its own—I am etc.,

CHARLES M. BEADNELL  
Surgeon Rear Admiral

Egham Surrey May 16

### Prevention of Cancer

SIR—It afforded me great pleasure to read Dr Alfred C Jordan's plea for a natural diet in the prevention of cancer (*Journal* April 30, p. 973). We have heard it stated by a certain research body that food has nothing to do with the occurrence of cancer but these conclusions are based on ill founded experiments which have but little bearing on the dietary of human beings. Dr W. Cramer in his recent article (April 16 p. 829) stressed the fact that cancer is a preventable disease and certainly a study of the incidence of occupational cancer due to such agencies as tar, paraffin and mineral oils shows that correct supervision of those working with carcinogenic substances can diminish if not altogether prevent the occurrence of that type of cancer. The more civilization progresses the more do we use carcinogenic hydrocarbons which have their origin mainly in the destructive distillation of coal, wood oil and even tobacco. If we protect the worker with carcinogenic substances from their poisonous actions surely we must protect the community from the everyday use of similar substances in diet. The use of carcinogenic foods is much more widespread than one might at first imagine. Do not such articles of food as the homely kipper, smoked ham, roast chicken and fried food in general contain carcinogenic hydrocarbons? Although the ingestion of extrinsic carcinogenic substances may be a factor in producing a local lesion such as a gastric carcinoma let us not forget that these substances have a general toxic effect which weakens the body's defences to intrinsic carcinogens—for example, oestrin.

Beck (1927) produced experimental tar cancer in animals the occurrence of which was much greater when intravenous injections of tar were given simultaneously. Fischer and Wasils found that small doses of arsenic likewise increased the occurrence of experimental cancer while Ebner, Klinge and Wacker (1925) noted that experimental tar cancer tumours appeared earlier and had a higher incidence in mice which had been fed on cholesterol than in control animals. A revolution in the feeding habits of civilized peoples is inevitable and a cancer mortality of 1,600 per million living in Great Britain calls for drastic and immediate action. After the indictment of amidopyrine as a cause of agranulocytosis and the placing of this substance on the poisons schedule its deadly effects immediately became noticeably rarer. Did not a Government of our time place a large tax on alcohol thereby diminishing the occurrence of cirrhosis and other sequelae of alcoholism? Similar drastic restrictions must be made sooner or later in respect of many common foodstuffs which are known to be carcinogenic and some far seeing

Minister of Health will doubtless consider such measures or enjoining a fitter Britain. Medical men could likewise further propaganda for the prevention of cancer and adopt such slogans as "Cancer of the stomach awaits you if you season your food and don't spoil your food by eating." Let us as a nation produce fit food or import them from our colonies and not be dependent on the products of synthetic chemistry as other less fortunate nations have to be—I am etc.

Whatever May 9

TOM G. S. HARKNESS

### The Origin of Constructive Variation

SIR—In your current number there is a review of the late Dr Albert Gray's book *The Basis of Tissue Evolution and Pathogenesis*. I should like to point out that neither the reviewer nor Dr Gray's editors seem aware that his essential apparatus was first publicly developed by myself in 1918. Your reviewer's piece of the whole book is so admirably adequate that you will I feel sure permit me to quote it in order to show that well known work of my own antedates it by twenty years.

The essay is based on the hypothesis that the variation which results in evolution are induced variations caused by the response to injury and the repair of tissues. The term injury is used by the writer in the widest possible sense and includes the idea of stimulus that in time of repeated repair from the effects of injury what formerly constituted an injury has become a stimulus. Thus the response to changes in environment takes the form of induced variation in contrast to the idea of spontaneous variation which is rejected.

Now in 1918 I read before the Zoological Society a paper on the function of pathological states in evolution. This paper somewhat amended and repaired appeared in 1920 in my book *Warfare in the Human Body* as the third chapter—Repair in Evolution. I will quote a few sentences from the chapter.

It then can be shown that disease has had a profound effect upon the evolution of all organisms and that analogous results are found in every kind of human constructive effort in such numbers as to suggest as a law that all great variational developments result not from a happy-go-lucky aggregation or small variation or from discontinuous variation whether of a Mendelian character or not but rather from partial failure and repair we seem to be in sight of a general principle of profound importance (p. 6.) "It is to be inferred from these considerations that the structure of an organism is not a congeries of minute fortuitous advantageous variations nor the gradual making of details in an orthogenetic line nor the result of large discontinuous variation due to chromosomal inheritance but a complex of definite reactions to definite stresses. The true theory of living structure is that its growth is neither casual nor to be seen but that it is what we may call in political language the opportunism of the organism as a whole. Every advance is a forced even a desperate experiment. Life like a hypothesis or a dam, is built by stopping up leaks (p. 79).

There is nothing original in Dr Gray's view of injury. I can trace the notion of it as an evolutionary factor no further back than Virchow but in *Malignancy and Evolution* published in 1926 when speaking of morphogenetic symbionts I wrote: "It is hard to say why such facts should not be regarded as relevant to the theory of transmission and the view I have taken that transmission occurs normally by injury to the germ plasma (p. 149). In a later collection of biological essays *The Serpent's Fang* (1930) I wrote that in the anatomy of the human body alone sufficient proof can be found to show that variations of actual structure which are not Mendelian since Mendelian mutations are not really specific characters at all always or almost always arise as

the result of disturbing stresses (p 89) It is not too much to say that the theory claimed for Dr Gray is largely the motive force of these three books, two of which are well known and have been favourably received by many leaders in the medical sciences

It should therefore be clear that I have made a continuous use of suggestive hypotheses which I myself welded long ago into a working apparatus and effective theory I may add that my last book, *Bio-Politics*, lately reviewed in your *Journal* applies the doctrine of constructive variation which I have called *Stress Breakdown and Repair* to life generally and social organization in particular—I am, etc,

London, May 15

MORLEY ROBERTS

### Wound Healing in Carcinomatous Patients

SIR,—Whether carcinoma of the stomach is very common here, or whether patients delay before taking notice of discomfort in the abdomen, or whether I am particularly slow to recognize the disease, I leave to the kindness of any who choose to criticize The fact remains that it has fallen to my lot in the past year or two to open the abdomens of a number of men to find non-operable carcinomata of the stomach I hasten to add that the diagnosis was made before operation in, I think, every case, but the laparotomy was always undertaken in the forlorn hope that the growth might be operable or the diagnosis erroneous The point I wish to bring to notice is that without exception all these patients wounds have healed very rapidly, leaving a thin linear scar such as one all too often hopes for and fails to procure in for example, appendicectomies This property of rapid clean healing is most striking in my experience, provided of course that the growth is not invading the abdominal wall What is the reason for it? The patients are in poor condition and do indeed die of their disease in a few weeks or months One would expect slow healing or even failure of union Does the carcinoma itself in some way favour the proliferation of fibroblasts, or is there an increased tendency in general to form firm fibrous tissue as a natural reaction to the presence of the tumour in the body?—I am, etc,

Cornwall May 10

L A RIDDELL

### Fractures of Neck of Femur

SIR—Mr R Watson-Jones (*Journal* May 7, p 1025) writes a characteristically brilliant letter yet I disagree with his very first statement Having nailed his fracture he refuses to remove the nail when he is satisfied that bony union has resulted from his procedure, being content to wait for post-mortem examination to satisfy my surgical curiosity I reduce all medial fractures of the femoral neck and then immobilize them with a trifling nail But when I am convinced that bony union has occurred I remove the nail—for the same reason that I remove a plaster in dealing with other fractures All routines have exceptions, and my very feeble and very aged patients are not subjected to a second operation

My reasons for removing the nail may be of interest There is no doubt from my observations that stainless steel and bone are unsatisfactory bedmates In almost all cases there is a reaction between the bone and the nail the bone undergoes necrosis—pressure or aseptic—and the neck is weakened In the vast majority of fractures of the femoral neck the fracture has occurred because of atrophy of its bony architecture—the fracture is

characteristically one which occurs in patients of advanced years That we can give the femoral neck temporary additional support by a stainless steel nail is no real advantage What we aim at is to reconstruct the bony architecture of the femoral neck This is possible with the help of the Smith-Petersen nail The nail should be placed either in the middle or above the middle of the femoral neck in the antero-posterior plane (I refer to medial fractures only), and in the middle of the neck in the lateral plane Having accomplished this and allowed time for soft tissue repair, the fractured limb is quite able to bear the full body weight In fact early weight bearing stimulates the reconstruction of the architecture of the femoral neck When we see the reconstruction of the calcar femorale radiologically, then it is wise to remove the nail, in order that the bone in its immediate vicinity may also be reconstructed In other words, our endeavour is to make the femoral neck even stronger than it was before the original fracture, since the fracture is generally caused by trivial violence through the atrophic bone of the femoral neck Consequently I would stress the importance of (1) accurate reduction of the fracture, (2) placing the nail away from the calcar femorale in medial fractures, (3) early weight-bearing, and (4) removal of the nail as soon as the architecture of the calcar femorale is reconstructed in order to strengthen the femoral neck in the immediate vicinity of the nail and to re-establish the neck more soundly than was the case before the fracture occurred

These conclusions are arrived at not on theoretical grounds but from practical experience To revert to theory, however, the explanation of Mr Watson-Jones's single unsatisfactory case from removal of the nail may be that he removed the nail too late, that the bony changes around the nail had resulted in such a degree of necrosis of the neck that when the nail was removed the neck was so weakened that trivial violence re-fractured it Mr Watson-Jones must be quite familiar with the patient who has an osteitis of the femoral neck due to the presence of the nail such that only the removal of the nail cures her symptoms I have no doubt that he removes the nails in these cases My contention is that he should go further and remove the nail at an earlier stage—that is, as soon as he is convinced that bony union has taken place In conclusion, I would like to join the ranks of the optimists who believe in the nailing operation for medial fractures I do most sincerely agree with Mr Watson-Jones's last statement—that Mr Eric Lloyd's aphorism, "the bad results of nailing are the results of bad nailing," should be stamped on every nail—I am, etc,

WILLIAM GISSANE

St James's Hospital, London, S W 12, May 8

### Treatment of Anterior Poliomyelitis

SIR—As a recent arrival from Australia I have been interested to hear the opinions of orthopaedic surgeons and others on the treatment of cases of paralysis suffered by Sister Kenny at Carshalton It seems that if results are not all that were expected Although facilities were given to Sister Kenny at Royal North Shore Hospital, Sydney, and at other clinics, it is by many orthopaedic surgeons and massagers in Australia that Sister Kenny has not in all cases lived up to her expectations It is thought that the abolition of splints is dangerous and that splinting does not aid muscle re-education—I am etc

E A BUCKLEY MBS  
Late Superintendent at Royal  
Shore Hospital Sydney

Bath, May 9

## Tuberculin in Diagnosis

SIR—I have read the recent correspondence on the subject of tuberculin reactions with some interest. It would be instructive to learn what evidence Dr Curre Wilkin and those who have written supporting him have of the value of the tuberculin reaction in the positive diagnosis of active tuberculosis. While there is general agreement that a negative test in the great majority of cases excludes the presence of tuberculosis I have been unable to find any convincing grounds for believing that a positive test is of any value in indicating the presence or absence of active tuberculous disease. The point is of considerable importance for if active tuberculosis be diagnosed on the sole finding of a positive tuberculin test and even if (to quote Dr John R. Gillespie, May 7 p 1026) 'six or nine months treatment with tuberculin makes it all right many healthy people may be subjected to unnecessary mental distress by being stigmatized as tuberculous. Moreover they may possibly be handicapped later for life insurance or even for employment—I am etc

London, S.F.1 May 3

J. R. FORBES

## Multiplicity of Special Diplomas

SIR—Even the small volume of correspondence in your columns that has arrived in India shows that the indiscriminate creation of postgraduate diplomas is far more widely condemned than I had imagined when I first introduced this subject. As I pointed out in the *Journal* of March 26, the medical profession should do all in its power to stimulate postgraduate study. At the same time the granting of series of obscure letters to be attached to one's name and used as a lever in obtaining appointments for which equally or better experienced men have applied is to be deprecated.

Probably one of the most complicated of specialties is venereal diseases yet no special diploma in this subject has been thought necessary nevertheless the Ministry of Health insists on adequate postgraduate training for any appointment in the specialty and certificates of having had training in a venereal centre under a specialist in this branch of the profession are invariably required before a new appointment is made. Could not a similar system be introduced into other specialties? Surely the possession of reasonably prolonged experience under a leader or any specialty should entitle one to a certificate of far greater value than the acquisition of any diploma obtained by good luck in passing an examination after a three weeks cram course such as has been advertised for the Diploma in Anaesthetics. Some of the Scottish universities already have the system of issuing certificates to undergraduates for having duly performed the work in any subject, and there is a lot to be said for introducing such a system of postgraduate studies. If the right to grant such certificates was limited to leaders of each branch of the profession the certificates would at least have some post-obtaining value and would be a considerable improvement on a system which permits a man who studies say, mental diseases in London to become a DPM in Edinburgh a Dipl Psych in Durham a DPsy and in Liverpool nothing at all.

A further point I would like to raise is the use to which diplomas obtained under the present methods are being put. Surely they show membership of some learned society or the possession of certain postgraduate experience and are not meant to be used as decorations to be attached to one's name with the idea of impressing the

general public. No one can object to a medical man indicating that he is a qualified practitioner by having on his name plate the letters MB or MRCS or such symbols of higher qualifications as FRCS or MD. But surely one is no more supposed to attach to one's name the initials of the vast number of unregistrable diplomas that are now procurable than one is expected to walk through the streets proudly wearing a medal obtained for proficiency in first year botany—I am etc,

H. M.

## The M.R.C.P. and Psychiatry

SIR—May I endorse the protest made by your correspondent A. M. O. in the *Journal* of May 14 (p 1071) against the policy which he declares the L.C.C. Mental Hospitals Department is adopting—namely that the promotion of medical officers of that department will in future be dependent on their obtaining the M.R.C.P. in addition to the D.P.M.?

I am personally interested in this matter because several conferences have recently taken place between representatives of the University of London the Royal Colleges and the Board of Control with a view to improving and stabilizing the requirements for the Postgraduate Diplomas in Psychological Medicine issued respectively by the University of London and the Royal Colleges. I was the senior representative of the University of London at these meetings and I have within the last few days been approaching the Minister of Health who is seriously concerned with the need for improving the conditions of both patients and doctors in mental hospitals. The Minister with characteristic foresight has agreed that the best means to achieve such a purpose is to secure an adequate supply of properly trained practitioners in psychological medicine.

In co-operation with representatives of the Board of Control I have suggested to the Minister that one of the first and most essential steps to improve the education and experience of practitioners entering for the D.P.M. is to provide opportunities for clinical study by certain measures for procuring salaried study leave for which purpose the local authorities would be urged by the Ministry to defray at least part of the cost and I am now without hope that the Minister of Health in framing his forthcoming Estimates may himself make some provision under this head.

I cannot help thinking that the L.C.C. has not consulted the Royal Colleges before adopting this policy for the Royal Colleges equally with the University of London are eager to make the Diplomas in Psychological Medicine the best preparation for medical officers wishing to make that subject both a special study and their subsequent life work. Possibly certain faults in the existing requirements for the Diplomas in Psychological Medicine may have led the L.C.C. to relegate them to a position inferior to the M.R.C.P. When these diplomas have been raised as they are in process of being to a standard ensuring the best possible training in psychological medicine it may perhaps be hoped that the L.C.C. will reconsider the propriety of demanding in addition what seems to me as well as to your correspondent the rather irrelevant and supererogatory qualification of the M.R.C.P.—I am etc

London W.1 May 14

E. GRAHAM LITTLE

SIR—Lest undue value be placed upon any particular qualification it appears well to remind ourselves that among the greatest contributors to the knowledge of

quixotic yet dogged attachment to a particular view or theory left him unabashed in a minority of one? Several striking essays and addresses delivered in quite recent years gave Boycott occasion to reveal himself as a highly individual thinker and critic, and I would particularly recall in this connexion his presidential address to the Pathological Section of the Royal Society of Medicine on the nature of viruses and the concept of living and non-living agents causing disease and growth, his charming and thought-provoking address entitled "Our Best Friend" at the opening of the winter session of UCH Medical School in 1933, when he dilated on the text "*When the body finds itself in trouble it does things which are helpful*", and lastly his unsigned contributions to the "Grains and Scruples" series in the *Lancet* written from his Cotswold home after his retirement. These with the *obiter dicta* liberally strewn in private correspondence with his friends will long keep fresh the memory of the real Boycott.

He was elected a Fellow of the Royal Society in 1914, and he held from McGill the honorary degree of LL.D. To his widow and two sons the sympathy of all will be extended.

J C G LEDINGHAM

Professor Boycott joined the British Medical Association in 1904, and in his early days of research was awarded several scientific grants. He acted as honorary secretary of the Section of Pathology at the London Annual Meeting in 1910 and vice-president of the same Section at Liverpool in 1912. He was a member of the Medical Research Council 1932-5.

### THE LATE DR MAXWELL TELLING

Dr E E Claxton writes: Dr Maxwell Telling was one of the outstanding medical men of the century. He held in turn the chairs of therapeutics, medicine, and forensic medicine at the University of Leeds, which in itself is a record. His whole life and career were spent in a search for truth in a courageous, pioneering spirit. In a letter to the *Lancet* in October, 1936, he told how he read a timid and tentative 'paper' before the Leeds Medical Society in 1905, entitled "A Plea for the More Systematic Employment of Psychotherapy." As he was only a junior the paper was received with kindly tolerance, but he remembered the outstanding comment was on my courage! This same courageous spirit led him to identify himself with the Oxford Group. While many of our leaders were declaring that no great advance was being made because of the lack of an 'indefinable something' Telling came boldly forward and declared that we were being held up because we had left God out of our lives. It was in the final phase of his search for truth that I met him at an Oxford Group house party. I well remember sitting next to him at a meeting, we were both strangers and first-comers, so we compared notes. I asked him what he thought of it all. He replied that it was right unquestionably right if everyone lived on the four standards of absolute honesty, purity, unselfishness and love we should have none of the present difficulties of the world—that was only common sense. I asked what was his psychological opinion. His answer was: Sound—absolutely sound. If you can get patients to tell their inner thoughts and fears they become free—there is no doubt about its soundness. But it was impossible to do anything about it: the cost was too great. And he said: I haven't the courage to face it. I met him later looking very troubled. He volunteered that he was reconsidering his decision but that he wanted to think it out calmly, free from bias,

in his own home. He was afraid (he humorously added) he knew what his decision would be. When I next saw him he was confirmed in his opinion that when man listens God speaks. This, he believed, formed the missing link in the chain of evidence he had discovered in his search for truth. In the end of his quest he accomplished the unity of his professional and spiritual life. His profession became the means of applying the result of his last investigation—that God's power can change and control human nature.

Dr FREDERICK ERNEST CHAPMAN who died on May 8 at his home in Hartlepool at the age of 50, was a Newcastle medical student, and graduated M.B., B.S. Durham in 1912. During the war he served both as temporary surgeon R.N. and as temporary captain R.A.M.C. Since then he had practised in partnership in Hartlepool, and was honorary surgeon to the Hartlepool Hospital. In his younger days Chapman was a noted Rugby footballer, playing many seasons for the Hartlepool Rovers and thirty-one times for Durham County. He played for England seven times between 1910 and 1914, and had the distinction of scoring the first try in the first international match at Twickenham in January, 1910, against Wales. Two years earlier he was a member of the side which toured New Zealand. He could play equally well on either wing, at centre, three-quarter, or full back, and even after long service over-seas found a place in the Durham County XV.

The sudden death at the early age of 32 of Dr FRANCIS GEORGE MAITLAND has come as a great shock to a large number of friends and patients. He died at Norwich on April 25 from a pneumococcal infection. Dr Maitland was educated at University School, Hastings, and Clare College, Cambridge, and took his hospital course at St Thomas's. After qualifying in 1930 he held resident appointments at St Thomas's, the Lying-in Hospital, York Road, and the Royal Surrey County Hospital, Guildford, and proceeded to the degree of M.B., B.Chir. before going to Norwich three years ago as partner to Dr Preston. He was devoted to his work, and because of this and his charming manner he quickly became established as a successful doctor. A man of wide interests, he would spend his leisure hours racing a Norfolk punt on the Broads, or listening to music, which he had studied since his boyhood. Francis Maitland was a public spirited man who gave valued service to the Norwich Lids Club as an honorary surgeon and to the St John Ambulance Brigade as divisional surgeon. He held the rank of captain in the 161st East Anglian Field Ambulance, R.A.M.C. (T), and was working on its behalf within a day of his fatal illness.

Dr JOHN WATKIN EDWARDS died at his home in Beckenham on April 26, aged 74. He received his medical education at Edinburgh University, and graduated M.B., Ch.B. in 1889. For over thirty years he practised in Middlesbrough, Yorkshire, where he held among other appointments that of medical officer of health for the Tees Port. In addition he was actively identified with musical activities in Middlesbrough, and for many years presided at the annual Eisteddfod. In 1921, following a breakdown in health caused by an accident, he gave up practice in the North and moved to Anerley, London, S.E., where he was in practice from 1922 to 1936. Here again he took a keen interest in public affairs in the district including the Penge and Anerley Branch of the League of Nations Union, of which he was president for several years, and the Penge and Anerley Philanthropic Society, of which he was president in 1930. Dr Edwards was a member of the British Medical Association for over forty years, and was chairman of the Cleveland Division in 1914-15 and of the Bromley Division in 1931.

Dr JAMES JACKSON MINOT founder of the B.T. Tuberculosis Association and father of Dr G. Richards Minot, Nobel Laureate, died at Boston April 30 at the age of 85.

## Medico-Legal

### PATERNITY EXCLUDED BY BLOOD GROUPS

The principal reason why so little has been heard in this country of blood group evidence in cases of disputed paternity has been that our law does not allow the magistrates to say to a woman applying for an affiliation order that she must submit to a blood test or withdraw her application. In many countries where this is allowed the evidence of the pathologist has proved of great assistance to justice in a troublesome class of case. In recent proceedings before the Marlborough justices the applicant expressed her willingness to co-operate in the test. Accordingly she, her child, and the man whom she alleged to be the father visited Dr G. Roche Lynch's laboratory and had specimens taken. Last Monday at the resumed hearing Dr Roche Lynch gave evidence that the mother's group was AMN, the baby's was AN and the man's was OM. He explained that a child with the N character in its blood must have either one N parent or two MN parents. With an MN mother therefore the father must be MN or N. In the present case as the alleged father was OM he could not be the real father of the child. The A and O factors had no significance in this case because the baby could have got its A character from the mother. The applicant's solicitor said he was quite prepared to accept Dr Roche Lynch's statement and the chairman of the Bench thereupon dismissed the application.

This case is therefore of the greatest importance for the future of blood group evidence in this country. The evidence could only have been given by consent and it pointed to an unconditional exclusion which the magistrates who had doubtless familiarized themselves with the scientific facts upon which blood group evidence is based accepted without question. Undoubtedly the time has come for Parliament to give a man accused of the paternity of an illegitimate child the right—or at any rate the opportunity, in the discretion of the magistrates—to clear himself by undergoing a blood test with the mother and the child. Legislation should however take several important factors into account the chief of which is that it should impose no hardship upon the applicant who after all is in an unenviable position and suffers under a considerable handicap. The cost is also a major problem, because the parties to affiliation proceedings are usually people of scanty means. Unless the test were carried out wholly or largely at the public expense an Act permitting magistrates to order it would be a dead letter. In practice it would not be ordered in more than a small fraction of all affiliation cases. In that fraction however where there is a difficult conflict of evidence the result of the test would in a statistical proportion of cases—about one in every three in which the man is not the real father—give the bench solid grounds for dismissing the application. It is difficult to see any good reason why this possibility should not be opened up by statute. It would produce a small but quite definite contribution to the better administration of justice.

### TYPHOID CONVEYED BY MILK

#### An Echo of the Bournemouth Outbreak

In August, 1936 typhoid fever broke out in Bournemouth and Poole and there were some 205 cases in Poole alone. The epidemic directed public attention to the whole problem of urban milk supplies and may in time prove to have been the beginning of a far-reaching improvement. One of its minor consequences was an action\* brought in the High Court by a number of persons who

stilled in the epidemic against a milk supply company whose milk had conveyed the infection to them. This fact is not disputed by the company. The infected milk came from a small holding which regularly contributed to the daily input of 1,600 gallons, and was part of a large dairy farm called Melly Hall Farm. The Company mixed the milk from this holding with that of other farmers all being a credited milk from licensed producers. The infection originated in a sewage effluent which unknown to the farmer and above his land entered a stream from which his cows drank. The plaintiffs Mr. A. H. Square and members of his household pleaded that the company had contracted and had also warranted by letter and by a brochure that their milk should be clean free from infection and fit for human consumption. The plaintiffs alleged that the company had broken this contract and warranty. They also sued for negligence on the ground that the company had failed to take proper precautions to ensure that the milk was pure and for breach of the statutory duty imposed by the Food and Drugs (Adulteration) Act 1928.

#### Submissions by Council

Mr. Norman Birckett K.C. appearing for the plaintiff read certain passages of the brochure and submitted that one who believed them would be misled that the milk supplied by the company was safe and clean. The company obtained their milk from thirty even sources and emptied it all into one tank. The risk of contamination was therefore great. The company had done nothing at all to ensure that the high-sounding words in their brochure were carried into effect. The assurances which the company gave the plaintiffs were untrue to the company's knowledge. The company refused any inspection and did nothing to see that the sources of their milk were conducted under hygienic conditions. The brochure was grossly misleading in creating the impression that the conditions were ideal. The representations had been false at the outset.

Dr. R. J. M. Horne the medical officer of health for Poole said that the company had co-operated with him to the best of their ability. The company's milk depots had a good standard of cleanliness and during a recent year he had written congratulating the manager on a year's analysis of very good milk. There was no method of testing milk for typhoid which could be carried out commercially.

Mr. R. P. Croom Johnson K.C. for the company submitted that the warranty which the plaintiffs alleged to have been broken applied expressly to a future supply of milk and breach of a representation as to the future could not be the ground of a legal claim. No one had suggested that the company could have known or were responsible for the contamination of the milk. There was no indication of recklessness or that the company which supplied 10,000 people were not taking every possible care to see that their milk was free from contamination. No one had given evidence that to bulk milk supplies into one tank was extraordinary or improper practice. The charge of fraud in the warranty was necessary in law in order to enable the other members of Mr. Square's household to recover damage although the offending article had not been sold to them. The manager had been in the milk trade a long time and had done everything that could be required of him and a charge of fraud against him was completely baseless. The cause of the infection was not even known to the farmer let alone the manager of the company. Even if the company had broken their warranty that was not the cause of the plaintiffs' illness for the illness did not arise from any want of cleanliness by the company or the farmer.

Mr. Birckett in reply said that the company's booklet described their model farm but did not say that the milk from that farm was mixed with a much larger supply from many outside sources. All his statements in it about the impossibility of contamination were false. The company had no organization which would enable them to supply as they claimed to do rich pure milk free from contamination. On the question of negligence if the company had required at

\* Square and others v. Model Farm Dairies (Bournemouth) Ltd. Times May 4 et seq.

the farm where the contamination occurred and had made an inspection, they might have found that there was a discharge of sewage into the stream. The fact that they had made no inquiry was strong evidence of negligence. They could have asked the local authority or the farmer. The discharge pipe could have been discovered by inspection.

Mr Justice Lewis ruled that there was no case for the company to answer on the charge of fraud, but that they must answer the charge of negligence.

#### Evidence for the Defence

Mr A J Newman, tenant of Merly Hall Farm, said it was used solely for dairying. He took every possible step to see that the business was carried on properly. Until the investigation by the medical officer of health he had no idea that anything was wrong with his milk or any suspicion that sewage was reaching the stream. The manager of the company had often visited his farm and inspected it. He had never used water from the stream, but the cows drank from it. His wife had died of typhoid, but he had not known the cause of her death until he had seen the death certificate. Each cow underwent a careful periodic test. They had been examined in June 1936, before he had received his licence to produce accredited milk and afterwards at regular intervals of three months. His wife had never assisted with the dairy work. Only after her death had he discovered that sewage was led in to the stream. The land where it was led in was occupied by someone else, and he had no right to go on it. Cross examined, Mr Newman said that the udder of each cow was washed when it was driven in for milking, and then dried with another cloth. The water used for cleansing the utensils came from a steel-lined well.

Mr J W Partridge, manager of the United Dairies depot at Wimborne, said that the bulking of milk was not at all exceptional. If London people had to wait while each lot of milk was separately handled they would not have their milk on the doorstep at six o'clock in the morning but six days later. It was never considered negligent not to test a particular consignment before bulking. There was no test for typhoid which would give a positive result in under five days. Merly Hall Farm had been properly and cleanly conducted.

Mr W F Long, managing director of the company, said he had been in the milk trade for fifty years, and before the outbreak he had no suspicion that there was anything wrong with his or any other milk supply. He had been to the farm many times even before Mr Newman had been its tenant, and before he had made his contract with Mr Newman he had thoroughly inspected it. Had he suspected any contamination of the stream he would at once have taken precautions to have it stopped or to see that his dairy was not connected with it. It was absolutely necessary for a supplier to know all the sources of his milk and the men who produced it. He paid all inspectional visits himself, and never gave notice. He hardly let a week pass without inspecting one farm or another. He had written the company's booklet himself and intended to convey in it that a very high standard of care was being maintained. He had in two years won the Dorset clean milk competition. He had been preaching and practising clean milk all his life. No form of inspection would have enabled him to see that there was typhoid in the stream in which the cows were watering.

#### Judgment

Mr Justice Lewis, delivering a reserved judgment on May 10, said that Mr Newman had beyond all doubt taken the greatest care to see that his milk was clean and pure. Mr Long was a truthful witness and so far as inspection was concerned could have done no more. All the milk bulked by the company was accredited milk obtained from licensed producers and the medical officer of health could find no fault with the company. There was no evidence that the statements in the booklet were untrue and no evidence of negligence. The plaintiffs, however, had another cause of action under the Food and Drugs (Adulteration) Act 1928, s. 2 (1) which provided that no person should sell, to the

prejudice of the purchaser, any article of food or any drug, which was not of the nature, substance, or quality of the article demanded. Apparently no reported case had ever been founded on that section before. The law, however, clearly allowed an aggrieved person to bring a civil action for an injury caused by breach of a statutory duty, even though the statute imposed a penalty as well. The latest illustration of that principle was *Monk v Warbey* (1935, 1 K B 75) in which the owner of a motor car lent it to a friend, though he was not insured against third party risks while the friend was driving, the friend injured a third party and the owner of the car was held liable, because he had committed an offence against the Road Traffic Act 1934. In his lordship's view 'the purchaser' included anyone who had suffered damage from the sale of food of an inferior quality from that demanded. If the company could have been prosecuted on the present facts they would have to pay damages now. Although they were morally entirely innocent, they were none the less guilty of a breach of their duty under the 1928 Act for Mr Square had asked them for clean and pure milk and they had not given him milk of that quality. The plaintiffs were therefore entitled to recover, and he awarded damages amounting to £865 and costs.

#### A FATAL DOSE OF PARALDEHYDE

Not long ago two nurses were found negligent in the High Court<sup>1</sup> for giving a patient six ounces of paraldehyde instead of six drachms. In that case it was said that the instructions had been written on a piece of paper by a staff nurse, and there was a dispute about whether she had written six ounces or six drachms. The Paddington coroner, Mr Ingleby Oddie, recently had to investigate a similar mishap. A lady patient was sleeping badly and her nurse rang up the doctor. He agreed that the patient should be given paraldehyde, and according to the nurse he said that the dose should be six ounces in eight ounces of paraffin. The doctor himself said in evidence that he had said, not six ounces, but six drachms. He would probably have seen to the administration himself, but he was distracted by his wife's fatal illness, and she died on the evening before the paraldehyde was given. In this case also the nurse said she wrote the dose on a piece of cardboard, but that, as the patient did not wish the card board to be kept, it was put on the fire. The nurse said she then copied the dose on to a piece of paper, but eventually tore it up because she did not think it of any importance. She had no wish to protect herself by doing so. The coroner, recording a verdict of death by misadventure, remarked that it seemed to him rather singular, if she had that piece of paper, that she did not produce it at once when she told the doctor the next morning that she could not rouse the patient. The doctor, in a moment of mental confusion, might have used the word 'ounces' instead of 'drachms,' but it was almost impossible to say what had really happened. The doctor was a very experienced practitioner but was suffering from great mental distress. Mr Oddie pointed out the importance when dealing with dangerous drugs, of using the utmost care and of giving written directions in prescribing them.

The danger of confusing ounces of paraldehyde with drachms may perhaps arise from the custom of prescribing the dose in a given number of ounces of paraffin. It is rather surprising to reflect that paraldehyde is not one of the many drugs which, by the Poisons Rules, must be sold under certain restrictions. It is a good deal more dangerous than many of the drugs in the fourth schedule of the Poisons List. The attitude of the family of a deceased lady was a model of generosity, for her mother declared that they bore no ill will nor did they make any charge against anyone, both doctor and nurse. It is shown by his mother the greatest kindness and care. Five years ago Dr C O Hawthorne in his *Short Essay*...

<sup>1</sup> *Strangeways v. Lumsden*, Clayton 1936 1 All E.R. 41

*Medical Topics* said wisely that the prescribing and ordering of medicines should be by written directions and for such purposes the telephone should be forbidden. He was referring to a recent disaster in which in overdose of eucaine had been given after a telephone prescription. No doubt more accidents are caused by this misuse of the telephone than are reported in the newspapers. The practitioner should impose on himself a strict rule never to trust the telephone for anything of which a misunderstanding may possibly lead to injury.

## Medical Notes in Parliament

Dr Walter Elliot has been appointed Minister of Health in succession to Sir Kingsley Wood who becomes Secretary of State for Air. Dr Elliot is succeeded in the office of Secretary of State for Scotland by Colonel John Colville. These and other Ministerial changes were announced on May 16.

Housing Bills have been before both Houses of Parliament this week. The House of Lords also discussed foreign affairs and the House of Commons unemployment. A debate on air rearmament was postponed because of the indisposition of the Prime Minister.

### Progress of Bills

In the House of Lords on May 16 the Baking Industry (Hours of Work) Bill and the Registration of Stillbirths (Scotland) Bill which have passed the Commons were read a first time. On the same day Lord Horder introduced the Funeral Directors (Registration) Bill which was read a first time.

On May 17 in the House of Lords the Eire (Confirmation of Agreements) Act received the Royal Assent.

The Select Committee of the House of Lords which will consider the St Bartholomew's Hospital Bill was fixed to meet on Thursday May 19.

The Criminal Procedure (Scotland) Bill was reported to the House of Commons from the Standing Committee on Scottish Bills on May 12.

On May 16 the Housing (Rural Workers) Amendment Bill passed through Committee in the House of Commons.

### The Capitation Fee for Juveniles

On May 12 Mr RHYS DAVIES asked the Minister of Health to state the reasons which induced him to allow the same capitation fee to panel doctors under the national health insurance scheme in respect of insured persons between 14 and 16 years when no medical certification was necessary as was paid from 16 and upwards when medical certificates were issued while at the same time allowing only 1s 9d per annum to approved societies by way of administration expenses in respect of these younger persons when 4s 6d per annum was regarded as reasonable to cover those over 16 years of age.

Sir KINGSLEY WOOD reminded Mr Rhys Davies that this matter was recently examined by a Court of Inquiry and the fee fixed in accordance with its recommendations.

Mr DAVIES: Is it not a fact that the right hon. gentleman offered terms very much below those mentioned in the question and has he not succumbed to the demand of the doctors for better terms?

Sir K. WOOD: No. This matter was investigated by a court of arbitration.

Mr MACQUISTEN: Does the right hon. gentleman know that the medical profession is spending large sums on pasteurization propaganda? Is it their own money and does not fall on anybody else?

Mr LOGAN: Is the right hon. gentleman aware that this sum is not sufficient for the work done and will he revise it?

### Cheap Milk Schemes

Mr W. S. MORRISON stated on May 5 that the Milk Marketing Board did not at present contemplate any extension of the experimental schemes in the Special Areas. The Government proposed to bring forward proposals for coming in co-operation with the industry a reduction in the price of liquid milk to local authorities generally for the purpose of their maternity and child welfare arrangements. Of persons eligible to participate in the four experimental schemes for the supply of cheap milk to nursing mothers and children under 5 years in the Special Areas the proportions that availed themselves of the facilities varied between 60 per cent in Farrow and 65 per cent in Whitehaven.

On May 9 Mr W. S. MORRISON replying to Mr Ridley said he was informed by the Milk Marketing Board that there had been an average increase of 0.1s pint or 61 per cent in the daily per capita consumption of milk in families participating in the experimental schemes for the supply of cheap milk to nursing mothers and to children under 5 years in the Special Areas.

Sir KINGSLEY WOOD stated on the same date that all the thirty-five authorities responsible for maternity and child welfare services in the Special Areas supplied additional nourishment in the form of milk to expectant mothers and about five of them did so at all stages of pregnancy. Twenty-two of the thirty-five authorities supplied other forms of additional nourishment to mothers; the great majority at all stages of pregnancy. In addition the scheme introduced by the National Birthday Trust Fund for providing other additional food for certain groups of expectant mothers was in operation in most of the Special Areas.

Miss WARD asked if the Minister of Health would consider making representations to those local authorities which did not supply milk and ask them to carry out what she understood was the approved policy of the Minister.

Sir KINGSLEY WOOD said he was following the points up.

### The Case of Francis Healy

On May 10 Mr MCGOVERN asked the Secretary of State for Scotland the date when Francis Healy was transferred from Gartloch Asylum to Perth Prison. It was then certified as sane the date of his removal from Perth Prison to Woodilee Asylum, the circumstances surrounding his removal and certification and who were the medical men who again certified him as insane. Mr WEDDERBURN, who replied said that Healy was discharged from Gartloch Mental Hospital on February 7 last, the medical superintendent being of the opinion that he had recovered from the mental condition from which he had been suffering. He was taken on that date to Perth Prison. Healy's mental condition subsequently gave rise to anxiety and he was kept under observation. On April 17 Healy was certified insane by the medical officer and the assistant medical officer of Perth Prison. On the following day he was removed under Sheriff's warrant to the Glasgow District Mental Hospital, Woodilee. Healy refused to leave the car in which he was taken to the mental hospital although every effort was made to induce him to do so. He had therefore to be forcibly removed.

Mr N. MACLEAN asked if an Act passed four years ago for Scotland did not provide that instead of such a case as this being examined by two official doctors of an asylum one of the examiners should have been an independent doctor. Why was an independent doctor not called in? Mr WEDDERBURN cited statutes to justify the action taken in the case under discussion.

### Drug Traffic Increase in China

On May 16 Mr D. ADAMS asked the Prime Minister whether his attention had been drawn to the greatly increased trafficking in drugs in China by Japanese and Korean traders under the control of the Japanese Government and whether he would make strong representations to every possible source to prevent a systematic demoralization of the Chinese people through these means. Mr BUTLER, who replied said he had

received reports to the effect that recently this traffic had increased considerably but he had no reason to suppose that this was the outcome of any systematic and deliberate plan.

Replying to a further question by Mr Adams, Mr Butler said that the Government was alive to this matter and was making the strongest possible representations on it. In answer to Mr Noel Baker Mr Butler said that no representations had been made to the Japanese Government.

Lieutenant Commander FLETCHER asked if there was not a great deal of evidence to show that the systematic demoralization referred to was part of the deliberate policy of the Japanese Government. Mr BUTLER said that the Government's information did not bear out this suggestion.

Mr NOEL BAKER: Is it not highly desirable that representations should be made to the Japanese Government so that the Chinese people should not be so demoralized?

Mr BUTLER: I will certainly consider the hon. member's suggestion.

On May 16 Mr D. ADAMS also asked the Prime Minister whether he was aware that in country markets in North China heroin and morphine were being systematically sold under the guise of medicine at prices as low as 1½d for a packet of heroin and whether steps were under consideration as to means of controlling the world production and distribution of these drugs.

Mr BUTLER agreed that these drugs were sold at very low prices in North China. As regards the world production and distribution of drugs, the licit drug traffic was already regulated by the Opium Conventions of 1912, 1925, and 1931. The British Government was taking every possible step to control and stamp out the clandestine manufacture and distribution of drugs on their territory. The appropriate committee of the League was shortly to consider what steps can be taken to limit the cultivation of the raw material from which all drugs were made.

### Effects of War Gas Poisoning

Sir HENRY MORRIS-JONES, on May 16, asked the Minister of Pensions whether he could give any information in regard to recent research work on sequelae to war gas poisoning, more especially in regard to deaths from respiratory diseases.

Mr RAMSBOTHAM said it would be impracticable to give complete information on research into the effects of gases used in the war. His Department was fully alive to these results, and he would arrange for his Chief Medical Officer to see Sir H. Morris Jones.

Sir H. MORRIS-JONES asked if the Minister was aware that recent evidence showed that the mortality rates in certain age groups of cases of war gas poisoning ranged from 40 to 70 per cent over the normal rate and whether, in view of that, he would consider a revision of the War Pensions Acts.

Mr RAMSBOTHAM said that the question on the order paper related to research. He could not describe what had been done within the limits of a question and answer.

### Mental Hospital Treatment of Voluntary Patients

On May 16 Sir KINGSLEY WOOD, replying to Mr Lyons, said that many local authorities were providing for the treatment of voluntary patients by the establishment at their mental hospitals of admission units, which were separate from the main institution but where all the resources of the hospital could be applied to the treatment of early cases. The number of persons presenting themselves for voluntary treatment at public mental hospitals had grown every year since the Mental Treatment Act came into force. Last year the voluntary admissions amounted to 8,414, which was 31.3 per cent of the total admissions to those institutions.

Mrs TATE asked if the Minister was aware that the real difficulty was that there was acute shortage of medical men trained in the treatment of these cases, that one of the few clinics for training medical men in this way was the Tavistock Clinic which was only supported by voluntary contributions and that there was urgent need of a larger supply of trained medical men.

Sir FRANCIS FREMANTLE asked if the Minister's reply included any statement in regard to the invaluable out-patient departments which were being established.

No replies were given to these supplementary questions.

### Medical Patents

On May 16 Mr D. ADAMS asked the President of the Board of Trade whether steps were being considered to reform the patent system in this country, either in the direction of compulsory dedication of scientific discoveries to the public or otherwise, so as to ensure to the public the benefits of discoveries made in scientific laboratories and to prevent the undesirable exploitation, *inter alia*, of patent drugs.

Captain WALLACE, who replied, said that Section 38A of the Patents and Designs Acts, 1907 to 1932, already contained special provisions designed to make medical patents more readily available to the public. Proposals for the amendment of the law by making compulsory the dedication of medical patents were fully considered by a Departmental Committee on the Patents and Designs Acts in 1931 which reported against any such amendment. The reasons for the conclusion were stated in paragraphs 185-201 of the report (Cmd 3479). There appeared to be no sufficient grounds for reopening the question of amending the Patent Law in this respect.

*New Medical Standards for Recruits*—On May 3 Mr HORE BELISHA, replying to Sir Alfred Knox, said that the chances which had been made in the medical and other standards for recruits had secured for the Army during the first quarter of this year an extra 1,733 men out of a total of 10,244 accepted.

*Unemployed and Disabled Ex Service Men*—On May 10 Mr ERNEST BROWN, replying to Mr Radford, said that on April 4 29,512 disabled ex service men were registered at employment exchanges as claimants for unemployed benefit or applicants for unemployment assistance allowances and 1,821 other disabled ex service men were also registered. Of the total of 31,333, 17,440 were men whose disabilities did not prevent them from following their usual occupations under ordinary industrial conditions, 13,608 were regarded as suitable for employment on work of a light nature, and the remaining 285 were suffering from disabilities which rendered it difficult for them to secure employment except with some institution specially designed for severely disabled ex service men or otherwise by special arrangement.

*Maternal Welfare in Durham County*—Mr WHITELL, on May 12, asked whether arrangements could be made to establish a maternity centre at Marley Hill, and thus prevent women having to travel the long distance to the Dunston centre. Sir KINGSLEY WOOD replied that he was in communication with the Durham County Council on this suggestion.

*Anti-gas Precautions in Government Offices*—Substantial progress has now been made with the training of civil servants in anti-gas precautions, and a survey has been made of the headquarter offices of many of the bigger departments and the accommodation most suitable for use as refuges earmarked. The survey of other offices is proceeding. Proposals in regard to refuge accommodation are being or are about to be, discussed by Departments with their staffs. The information was given to the House on May 5 by Col. J. Colville.

*Dental Benefit*—In Great Britain 5,400 approved societies and branches with a membership of 13,070,000 have in 1937 dental benefit in their current additional benefit schemes. 350 societies and branches with a membership of 17,000 have additional benefit schemes which do not include dental benefit while 1,150 societies and branches with 1,400,000 members have no disposable surplus from which additional benefits may be provided.

### Notes in Brief

Sir Kingsley Wood has received no notification from the Corporation of Liverpool intend to close certain day centres in that city. He is however in communication with about two complaints he has received in the matter.

In applying to research on chemotherapy an additional grant of £ 0000 provided by Parliament the Medical Research Council will obtain the co-operation of industry. Steps are being taken to ensure that scientific medical men and manufacturing chemists are brought within the scope of the scheme.

The Government of Jamaica is endeavouring to stimulate the local production of milk and other animal and vegetable products of high nutritive value. Practical education on proper nutrition is given at schools throughout the island at which midday meals are provided for the children.

The numbers of ex-Servicemen receiving in-patient treatment in Ministries of Pensions hospitals in 1936 1937 1938 were respectively 5635 5045 and 7855.

## The Services

### HONORARY SURGEON TO THE KING

Major General W B Purdon DSO OBE MC late RAMC, has been appointed Honorary Surgeon to the King. Vice Major General O Jevors CB DSO late RAMC who has retired.

### DEATHS IN THE SERVICES

Lieutenant-Colonel ASHER LEVENTON CIE Bengal Medical Service (ret.) died at Goddaiming on April 6 aged 65. He was born on April 29 1870 the son of the Reverend Israel Leventon Jewish minister Leicester and was educated at Trinity College Dublin and in the Catholic University. During his time in the L.R.C.P. and S.I. in 1894 and subsequently the F.R.C.S.I. in 1906 and the D.P.H. of the Irish Colleges in 1907. He entered the Indian Medical Service as Surgeon Lieutenant on July 29 1895 became lieutenant colonel on January 29 1915 and retired on April 29 1925. He received the CIE on June 2 1922. Most of his service was spent in civil employ in Assam and Eastern Bengal. In 1908 he was appointed Civil Surgeon of Dibrugarh and superintendent of the Berry White Medical School and in August 1913 superintendent of the Campbell Medical School at Calcutta. He had been a member of the British Medical Association for twenty-eight years.

Lieutenant-Colonel HORMANJI DADABHAI MASANI Bombay Medical Service (ret.) died at Cateham on May 12 aged 87. He was born on October 27 1847 and was educated at Bombay University where he took the diploma of L.M.S. in 1873. From 1874 to 1876 he served as a civil assistant surgeon in Bombay. He then came to England and took the M.R.C.S. L.R.C.P. in 1876 and passed for the Indian Medical Service which he entered as surgeon on March 31 1877. He became surgeon lieutenant colonel after twenty years service and retired on January 16 1898. He spent his service in military employ and served in the Afghan War in 1879 (medal) in the 1890 campaign on the North West Frontier of India and in the operations against Mazrui rebels in East Africa in 1896 (medal).

Major DOUGLAS HAMILTON COATS RAMC died in London on April 26 aged 45. He was born on August 28 1892 and was educated at Glasgow University where he graduated M.B. Ch.B. in 1916. He took at once a temporary commission as lieutenant in the Royal Army Medical Corps from May 1916 and became temporary captain after a few days service. He took a permanent commission as lieutenant from November 4 1919 and became a major on May 4 1928. He served for the last two and a half years of the war of 1914-18. He had been a member of the British Medical Association since 1919.

Captain CHARLES FREDERICK MAYO-SMITH IMS died at Razmak on the North West Frontier of India on January 31 aged 50 while serving in the late frontier campaign in Waziristan. He was educated at St. George's Hospital and qualified M.R.C.S. L.R.C.P. in 1931. He took the M.B. B.S. London in 1934 and joined the Indian Medical Service on May 1 1936. He had been a member of the British Medical Association since 1932.

## Medical News

The House of the British Medical Association including the Library will be closed for the Whitsun holiday from 5 p.m. on Friday June 3 to 9 a.m. on Tuesday June 7 (Library 10 a.m.).

Sir William Willcox will deliver the Cavendish Lecture on Toxicology with Reference to its Criminal Aspects before the West London Medical-Chirurgical Society at Kensington Town Hall on Wednesday June 1 at 8.30 p.m. Reception from 8 p.m. and the annual conversazione and medical and surgical exhibition will follow the lecture.

Three public lectures arranged by the National Institute of Industrial Psychology under the Heath Clark bequest will be given on May 25 May 30 and June 1 at 5.40 p.m. at the London School of Hygiene and Tropical Medicine Keppel Street Gower Street W.C. The subject this year is "Industrial Relations in the United States and Great Britain" and the lecturers are Dwight L. Palmer Ph.D. C.H. Northcott Ph.D. and Professor John Hilton. Admission is free without ticket.

The annual dinner of the British Orthopaedic Association will be held at the Langham Hotel on Friday May 27 at 8 p.m.

A joint meeting of the Royal Sanitary Institute and the Royal Sanitary Association for Scotland will be held at the Royal Technical College Glasgow on Friday May 27 at 5.15 p.m. when a discussion on "Air Raid Precautions" will be opened by Lieutenant Fraser Chief Air Raid Precautions Officer Glasgow who will deal with attacks from the air. Mr. Thomas Somers who will describe the city engineer's part in air raid precautions schemes and by Dr. William C. Gunn who will explain the medical services.

A meeting of the Medical Section of the British Psychological Society will be held at the Tavistock Clinic Malet Place W.C. on Wednesday May 25 at 8.30 p.m. for a symposium on "Some Problems Arising in the Adoption of Children".

The annual meeting of the Liverpool Psychiatric Clinic will be held at Liverpool Town Hall on Tuesday May 24 at 4.40 p.m. when the speaker will be Dr. H. Crichton Miller.

The seventeenth international neurological meeting will be held in Paris on May 31 and June 1 at La Salpêtrière when a discussion will be held on the pupil in neurology. The general secretary is Dr. Crouzon 80 b Avenue de Jena Paris 16e.

The third congress of the Italian Society of Gastroenterology will be held at Padua on June 19. The subject for discussion is disorders of the digestive system due to circulatory disturbance. Further information can be obtained from the secretaries A. Allodis Corso Re Umberto 5 bis Turin or A. Bonadico via Crescenzo 19 Rome.

The fiftieth anniversary of the foundation of the German Society of Internal Medicine was celebrated from March 28 to 31 at Wiesbaden where its annual meeting has always been held since 1909.

The first number of the *Harrogate Spa Medical Journal* was published last month under the auspices of the Harrogate Medical Society with a send-off message by Lord Horder.

At the meeting of the Central Midwives Board for England and Wales on May 5 the chairman reported that the National Birthday Trust has decided to award four scholarships each of £12 10s. to candidates attending the residential courses held in 1938 in preparation for the Board's midwife teachers' examination. The cordial thanks of the Board were conveyed to the National Birthday Trust.

Dr. Leonard Findlay has been elected a Corresponding Member of the Société de Pédiatrie of Paris.

A grant of £200 000 has been made available to university institutions towards the capital cost of increased facilities for physical training and recreation. This arrangement is made with the concurrence of the Treasury between the National Fitness Council for England and Wales and the University Grants Committee.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended May 7, 1938

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland Median values for the last 9 years for (a) and (b)

Figures of Births and Deaths and of Deaths recorded under each infectious disease, are for (a) The 126 great towns (123 in 1937) in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns (9 in 1937) in Northern Ireland

A dash — denotes no cases, a blank space denotes disease not notifiable or no return available

§ Includes primary form in figures for England and Wales (administrative county) and Northern Ireland

## EPIDEMIOLOGICAL NOTIS

## Small pox

During the week under review a case of small pox was notified at Gravesend and admitted to the Isolation Hospital. No connexion has been traced between this case and the case of small pox which occurred in a liner some weeks ago.

**Nigeria** During the week ended March 26 69 cases of small pox were notified with 170 deaths. Tanganyika 162 cases of small pox with 5 deaths were reported for the week ended April 23. Hong Kong 24 cases of small pox and 35 deaths were notified in the week ended May 7 in the previous week there were 55 cases with 40 deaths. The outbreak in Hong Kong has been attributed to the influx of refugees from Canton and neighbouring ports. From the beginning of the year to April 9 a total of 1925 cases was reported with 1507 deaths. An intensive vaccination campaign has been carried out during the last three months when 600,000 vaccinations have been made. United States During the week ended April 30 471 cases of small pox were notified compared with 417 in the previous week.

## Enteric Fever

Notifications of enteric fever in England and Wales continue to drop there have been 8 cases in the week under review compared with 20 cases in the previous week. The outbreak of paratyphoid fever at Cardiff appears to have ended no cases being notified during the week. On the other hand notifications in Scotland have risen from 7 to 41 among which there were no deaths. Of the 41 cases there were 1 in Glasgow 1 in Edinburgh and 39 in Roxburgh County. The 39 cases belong to an outbreak in Hawick where 73 cases had been notified by May 16 with 1 death in a girl 22 years old. A press report on May 17 under the heading 'Typhoid Spreads' stated that 92 people are now in hospital. Although there is nothing to suggest that water is the source of infection the water supply has been chlorinated as a precautionary measure.

## Diphtheria and Scarlet Fever

Notifications of diphtheria appear to be on the decline in England and Wales. London Scotland, and Northern Ireland. In Eire a slight increase was recorded. With the exception of London where notifications have been about the same as last week there has been a decided increase in the incidence of scarlet fever in England and Wales. Scotland and Ireland. The figure for England and Wales is in excess of the median value for the last nine years while the figure for London is considerably less. Compared with last week and the corresponding week last year the fatality from scarlet fever has diminished in the principal towns of all areas. In Northern Ireland no deaths were recorded during the week under review.

## Primary and Influenzal Pneumonia

The notifications of primary and influenzal pneumonia in England and Wales showed a drop compared with last week—1222 against 1370—and deaths from influenza dropped from 63 to 54. In Warwickshire 111 (115) cases were notified of which 75 (91) were in Birmingham and 15 (9) in Coventry. In the West Riding (Yorks) there were 125 (163) cases of which 39 (26) were in Sheffield and 17 (35) in Leeds. The figures in parentheses denote notifications in the previous week. During the week the deaths from influenza were Birmingham 4 (11) Coventry 3 (0) Sheffield 3 (1) Leeds 2 (0). The figures in parentheses denote deaths in the previous week. In London notifications have risen from 72 to 85 and deaths were the same as last week—namely 8. In Scotland notifications of primary pneumonia were 273, 2 less than in the

previous week there were 9 cases of influenzal pneumonia (the same as last week) and 3 deaths (1 more than last week).

## Measles

In the 126 Great Towns in England and Wales there were 32 deaths from measles compared with 35 in the previous week of these 13 (7) occurred in London 3 (2) in Sheffield and 2 each in Portsmouth (0), Bury (0), Kingston upon Hull (3), Manchester (0). The figures in parentheses refer to the deaths in the previous week. During the week 712 cases were reported from the L.C.C. elementary schools compared with 1825 (the week following Easter vacation) in the previous week. The average daily admissions to the L.C.C. fever hospitals were 45 compared with 60 in the previous week while the number of cases of measles under treatment in these hospitals on Friday May 6 was 1718 compared with 1975 on April 29 and 2123 on April 22. On the same day there were under treatment in the L.C.C. fever hospitals 1076 (1132) cases of diphtheria 808 (775) cases of scarlet fever 295 (287) cases of whooping cough. The figures in parentheses refer to the numbers recorded in the previous week. The notifications in the eleven metropolitan boroughs in which measles is notifiable were for the week ended May 7 406 (581) distributed as follows: Battersea 36 (69) Bermondsey 38 (37) Finsbury 23 (24) Fulham 37 (55) Greenwich 51 (121) Hampstead 17 (20) Lambeth 51 (86) St Pancras 34 (53) Shoreditch 28 (29) Southwark 28 (50) Stepney 31 (59). The figures in parentheses refer to the numbers in the previous week. In Scotland 461 cases of measles were recorded compared with 656 in the previous week the figures for Glasgow were 186 (304) Dundee 96 (126) Aberdeen 71 (94) Edinburgh 26 (67) Falkirk 27 (11). The figures in parentheses refer to the numbers in the previous week. During the week under review there were 17 deaths from measles in the 16 principal towns of Scotland compared with 27 in the previous week of these 6 occurred in Glasgow 4 in Dundee 2 each in Edinburgh Aberdeen and Perth and 1 in Coatbridge. In Northern Ireland there were 12 cases (all in Belfast) of measles with 3 deaths 2 of which occurred in Belfast and 1 in Lurgan. During the week there were 2 deaths from measles in Eire both in Dublin.

## Psittacosis

At Newcastle on April 11 a case of psittacosis was notified in a dealer in budgerigars. The suspected birds have been destroyed.

## Typhus

Typhus continues to be prevalent in Africa although in some districts epidemics are abating. Algeria During the week ended April 23 there were 31 cases compared with 35 reported in the previous week. Of the 31 cases 25 were at Constantine and 6 at Algiers. Egypt During the week ended April 29 there were 177 cases of typhus with 22 deaths compared with 149 cases and 22 deaths in the previous week. The cases were distributed thus: Beheira 59 Minufiya 41 Qena 26 Gharbiya 21 Aswan 14 and smaller numbers in other districts. Morocco During the same week there were 168 cases compared with 198 in the previous week mainly distributed as follows—Chaouia 48 Marrakesh 40 Rabat 24 Casablanca 13. Europe In Poland during the week ended April 23 there were 108 cases of typhus with 8 deaths. The departments with more than 10 cases were Wilno 18 cases with 1 death Polisia 16 cases with 2 deaths Kielce 13 cases with no deaths Wolhynia 13 cases with 3 deaths. In Rumania during the week ended March 15 160 cases of typhus were reported (132 in the previous week) occurring mainly in Orhei 24 Balti 14 Hotin 12 Cahul 11. In Yugoslavia during the week ended April 17 there were 35 cases (43 in the previous week) distributed as follows: Drina 23 Zeta 19 and 1 each in Danube Lit oral and Vardar.

# Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager. Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House, Tavistock Square, W.C.1.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

THE LITERARY ADDRESSES ARE  
EDITOR OF THE BRITISH MEDICAL JOURNAL, Antology, Westcent London.

SECRETARY, Mediseera Westcent London.  
The address of the B.M.A. Scottish Office is 7 Drumsheugh Gardens, Edinburgh (telegrams Associate Edinburgh telephone 24361 Edinburgh) and of the Office of the Irish Free State Medical Union (I.M.A. and B.M.A.) 18 Kildare Street, Dublin (telegrams Bacillus Dublin telephone 62550 Dublin).

## QUERIES AND ANSWERS

### Finger-prints of Twins

Dr R. COTLER (Liverpool) writes: In *Minor Medical Mysteries* (p. 2) Dr Leonard Williams says: "But perhaps the most interesting as it is certainly the most surprising point of similarity in like twins is the fact that not only their finger prints but the whole of what is known as the friction surfaces of their hands and feet are frequently found to be identical." On the other hand Sir James Crichton Browne in *From the Doctor's Notebook* (p. 68) quotes with approval evidence given at Cardiff by Inspector Greville.

In finger print identifications the authorities never make a mistake. A mistake would destroy the whole value of the department. It is impossible to make a mistake even in twins the finger marks are totally different. I have always been under the impression that the finger prints of twins—even of uniovular twins and irrespective of whether the single ovum from which these twins developed originally possessed two nuclei or a single nucleus which after fertilization divided into two blastoderms—have never been shown to be identical. In view of the diametrically opposed contentions of the two high authorities whom I have quoted I should be grateful for the opinions of those who possess more knowledge of this subject than I.

### Sulphanilamide and Breast Milk

J. I. B. writes: I would be glad to learn of any change in the quality of the breast milk or any effect on the health of the infant observed after the administration to the mother prophylactically or curatively of sulphanilamide compounds. In one case in my practice a morbilliform rash appeared on the fourth day following the administration of prontosil album to the mother; no untoward effect on the general health of the infant was noticed. Is this experience general?

### Preparation of Measles Serum

J. S. M. asks for instructions regarding the domestic preparation of serum from a convalescent measles case.

It is unwise for anyone not having at his disposal the services of a properly equipped laboratory to prepare serum on account of the possibility that accidental contamination may occur in the process. Laboratory procedures include addition of disinfectant and filtration to ensure sterility. Where serum is not available whole blood

(double the dose of serum) may be injected immediately after withdrawal into the leg muscles of contacts. Members of the family preferably parents only should be employed as donors, in view of the possibility of transmission of syphilis.

### Menostaxis

"A. H. I." writes: I have a female patient, aged 25, who has been married ten years and is sterile who suffers from almost continuous uterine haemorrhage. Menstruation started at about the age of 15, and was irregular and scanty for three years since when she has had this present trouble. There is apparently no physical abnormality. Curettage has been undertaken three times without any result. I shall be glad of any advice, particularly with reference to endocrine therapy.

### Ill health from Coal-gas Leaks

"R. H." writes: I should be grateful for information of the most recent work on ill health caused by the unsuspected leakage of coal gas in minute quantity from loose taps or erosion of pipes. I have good reason to suspect that a large amount of ill health might be prevented by scrutinizing the gas fittings, especially in old houses. I want to know (1) the most reliable method of proving the presence of CO in the air of living rooms (2) the presence of CO in the blood of living persons suffering from chronic ill health.

## LETTERS, NOTES, ETC.

### Sidelights on Syphilis

In an article on "William Shakespeare Syphilographer" by Walter E. Vest contributed to the March number of the *West Virginia Medical Journal* numerous and appropriate quotations from his works illustrate the poet's familiarity with syphilis, which he discusses frankly under such synonyms as 'malady of France', Neapolitan bone ache, pox and 'the infinite malady'.

To aid the campaign against syphilis, the Société Française de Prophylaxie Sanitaire et Morale has issued a stamp (65+25 centimes light mulberry in colour) depicting the symbolic figure of France holding an infant—the future race—in her arms. The legend reads: 'Pour sauver la race'.

### Medical Postage Stamps

Jean Baptiste Charcot (1867-1936), the French physician and explorer, is strikingly portrayed on a bluish green 65+15 centimes stamp with the legend 'Jean Charcot. Sociétés Œuvres de Mer'. In commemoration of the 10th international leprosy congress at Cairo an artistic set of three oblong Egyptian stamps has been issued: 5 milles brown, 15 violet and 20 blue. The central design shows a branch of hydnocarpus the seeds of which yield an oil used in the treatment of leprosy.

### Medical Golf

The eighth spring meeting of the Sussex Medical and Dental Golfing Society will be held on the links of the Crowborough Beacon Golf Club on Sunday, June 5. In the morning there will be 18 holes medal play under handicap and in the afternoon four ball foursomes against bogey. S. J. D. C. 14.

### Corrigendum

In epitome paragraph No. 405 which appeared in issue of May 14 at p. 81 the reference to F. R. B. A. C. 1 paper on Nicmann Pick's disease was given as F. R. B. A. C. 1 Child October-December 1937 p. 245. It should have read *Brit. J. Child Dis.* October-December 1937 p. 245.

### The Adreno-genital Syndrome

We regret that the footnote in the first column of p. 25 of last week's issue (May 14) gave incorrect full name of L. R. Broster's book *The Adrenal Cortex*, 1937. This work published by Chapman and Hall, 1937, 257 pages, and the price is 15s. net post paid.

## Medicine

### 412 Actinomycosis of the Lungs

F. BAUDICH (*Z. Tuberk.* 79 228) describes a fatal case of actinomycosis and tuberculosis of the lungs in a blacksmith of 47, whose mother, brother, and first wife had all died of pulmonary tuberculosis. The disease began in March 1933 with a cough, some sputum, and fever, followed, on a cold, in September the patient began to complain of severe neuralgic pains in the right chest and dyspnoea. In December there was haemoptysis, and tubercle bacilli were found in the sputum for the first time. An abscess in the back also developed and was aspirated many times; no tubercle bacilli were found in the pus but in February 1936 fusiform bacilli and streptothrix were seen. New abscesses on the shoulder and the elbow and numerous fistulous openings made their appearance. The patient's condition became steadily worse and he died on April 4, just one year after the onset of the disease. The diagnosis of pulmonary actinomycosis is extremely difficult. Largely because of the various routes by which the infection may enter the body and reach the lungs the disease does not present a uniform picture in any given case; moreover a coincident active tuberculosis as in the present case may make the diagnosis still more difficult. Cough, dyspnoea, and neuralgic pains associated with fluctuating thoracic tumours should be regarded as highly suspicious but a radiograph may not show any characteristic peculiarities, nor are bacteriological or biological investigations always conclusive. In treatment potassium iodide, x-rays, and possibly operative measures may be tried.

This study, begun in October 1932, was intended as a check on the monograph published by Howard F. Root from Joslin's Hospital in Massachusetts. 100 of the author's patients came from Oslo and the remaining 200 were from rural communities. Surviving as controls were Pirquet investigations of the healthy population at different ages in both town and country in Norway. As the author's tables show, the proportion of positive Pirquet reactions was approximately the same for the diabetics as for the controls. This observation gives no support to Root's statement that diabetics show a comparatively marked susceptibility to infection with tuberculosis. In other respects Hertzberg's findings coincide in the main with those of Root. Hertzberg has studied the records of 400 consecutive cases of diabetes treated in his hospital during the past four to five years, and in this material has found thirteen cases complicated by active pulmonary tuberculosis and one by tuberculosis of the spine and of the glands of the neck. This tuberculosis morbidity among diabetics of 3.5 per cent compares unfavourably with the tuberculosis morbidity of Norwegians in general (at most 1.5 per cent). In as many as ten of the thirteen cases of active pulmonary tuberculosis the signs of the disease appeared after the diagnosis of the diabetes. As for the behaviour of the pulmonary tuberculosis it corresponded in the main with that of pulmonary tuberculosis in persons not suffering from diabetes, and among the author's cases were some in which the tuberculosis ran a mild course and proved amenable to treatment.

## Surgery

### 415 Peptic Ulcer and Cancer of the Stomach

P. E. BLACKERBY and F. W. CALDILL (*Sth. med. J.* February 1938, p. 161) describe an epidemic of 400 cases of cerebrospinal meningitis in Kentucky in 1936. As in previous years most cases occurred in March and April, the industrial area was chiefly affected, and extension along much travelled routes could be traced. Cases were most numerous in the age group 1 to 4, decreasingly frequent from 5 to 50, and thereafter again more frequent. From infancy to 28 years males were nearly twice as commonly affected as females. The mortality rate was 25 per cent; it was greatest in the group over 50, next highest at ages 1 to 4 years, and least from 5 to 9. It was not felt that the general swabbing of throats and subsequent isolation of carriers lessened the incidence. There was little difference in mortality in cases treated by anti-meningococcus antitoxin and by anti-bacterial serum (20.2 and 25 per cent respectively), but in reply to the discussion on his paper Blackerby stated that in a series of forty-two untreated cases, diagnosed on clinical and epidemiological grounds but without bacteriological confirmation, the mortality was 85.7 per cent. In 136 cases in which both bacteriological diagnosis and accurate treatment records were available the fatality rate was twice as great among those treated at home as among those in hospital. Comparison of the date of institution of treatment with mortality gave evidence that early treatment facilitates recovery, but that apart from treatment the chance of survival improves if the patients live beyond the fourth day.

H. B. WILF (*Acta chir. scand.* February 28 1938, p. 433) has investigated the possible relationship to gastric and duodenal ulcer of 609 proved cases of cancer of the stomach observed in the period 1924 to 1933 in a hospital in Lund, Sweden. The diagnosis of cancer was based on the findings at operation in 336 cases and on radiological post-mortem or clear-cut clinical findings in 233 cases. The male and female cases numbered 233 and 186 respectively. In as many as 489 cases (80 per cent) there was no evidence of previous ulceration of the stomach judging by clinical, radiological, operative or post-mortem findings. In the remaining 120 cases there were such findings, but sixty-nine of these cases could be dismissed because the evidence of ulceration was unconvincing (in many cases a history of prolonged dyspeptic symptoms did not tally with the characteristic picture of gastric ulcer). Thus there remained only fifty-one cases (8.3 per cent) in which there was a certainty, or a considerable likelihood of gastric or duodenal ulcer having preceded the cancer. In nine cases (15 per cent) the microscopic examination of the new growths suggested that degenerative changes had taken place in ulcers. The author records in detail five cases in which radiological examinations conducted over a period of two to five years before cancer of the stomach had been diagnosed had made it possible to follow the course of certain ulcers in which malignant disease had ultimately developed.

### 416 Mikulicz's Metaphyseal Osteodystrophy

G. HERTZBERG (*Nord. med. Tidskr.* February 19, 1938, p. 295) has undertaken a study of 300 consecutive cases of diabetes admitted to the Rikshospital in Oslo, testing every patient with the Pirquet reaction, and noting the cases in which clinical evidence of tuberculosis was demonstrable.

G. MORACA (*Riv. Chir.* January 1938, p. 20) records the case of a youth aged 19 on whom he operated for a bony tumour of the shaft of the humerus. The growth consisted of a compact cortex continued into a spongy and vacuolated osteoid trabecular tissue. The dilated medullary cavity was filled with lamellar osteoid tissue like a mass of fine straws. Histological examination showed rarefaction and decalcification of the bony

trabeculae which were replaced by fibrous connective tissue. This histological structure, which resembled that of Recklinghausen's osteitis fibrosa, justified the case being regarded as a circumscribed form of the disease which Mikulicz described under the name of the metaphyseal osteodystrophy of adolescents. These cases are not connected with parathyroid deficiency.

417

## Sympathectomy

The arguments against the treatment of peripheral vascular disease by sympathectomy are discussed by GEZA DE TAKATS (*Arch intern Med* December, 1937, p 990). In addition to selected cases of Raynaud's and Buerger's disease certain cases of poliomyelitis and reflex dystrophy make up the total of fifty patients so treated at the author's clinic and chosen out of a total of 180 patients attending the clinic for these disorders. Twenty-four of the patients were observed for periods of from one year to seven years and the evaluation of results is based on this series alone. Although the peripheral vessels will regain their previous tone a short time after operation and will contract and dilate in response to local stimuli, yet, according to the author, they will be relieved of the continuous or intermittent barrage of stimuli conveyed to them before operation by the efferent sympathetic pathways. They will therefore not respond to heat and cold affecting the whole body neither will they contract as a consequence of emotional upsets. The oxygen saturation of the venous blood should be estimated before and after the operation, and no clinical benefit is to be expected in cases in which no post-operative rise in the oxygen saturation has occurred. Post-operative regeneration of fibres is only possible if simple section of the trunk of the sympathetic chain is performed. Should such regeneration occur after removal of the trunk with its ganglionated fibres it must be assumed that some of the post-ganglionic fibres escaped section and not all the excitor ganglia were removed. However the regeneration only concerns the lower centres and does not re-establish connexion with the higher centres. Central and reflex stimulation of the vessels, therefore will not be possible. Recently the author has performed pre-ganglionic section in diseases of the upper extremity to avoid the increased sensitivity to hormones which is said to occur when post-ganglionic degeneration has taken place, lumbar sympathectomies are always pre-ganglionic in type. Sympathectomy was uniformly successful in patients suffering from poliomyelitis with vasospasm and when performed for causalgia and traumatic osteoporosis. The author summarizes his attitude by saying: "Operation on the sympathetic nervous system is worthy of consideration for selected patients with peripheral vascular disease."

## Therapeutics

## 418 Measles Prophylaxis with Placental Extract

F. ROHR (*Dtsch med Wschr* March 18, 1938, p 413) has found in practice that the parents of convalescents from measles are apt to grudge their services as donors of serum to other children threatened by measles. As for adult donors by the time they have been tested with tuberculin and for syphilis, the potential benefits of their sera are liable to be much diminished by the delay. Accordingly the author has made use of a placental extract which he administered to thirty-five children who had not hitherto contracted measles but who had been exposed to infection. In the course of a year small groups of these children had on eleven occasions been exposed to infection. In every case but one 15 cc of the placental extract was injected on the same day that the measles rash appeared in a contact case. In twenty-nine cases no measles developed after the injection and in three cases the subsequent outbreak of measles

was mild. Thus there were only three cases in which the injection appeared to have no effect as a preventive of typical measles. In one of these three failures, the six months-old child was already much debilitated at the time of the injection, which gave rise to a hard swelling, which disappeared completely in due course. Apart from this case, there was no local or general reaction to the injection. The immunity thus conferred was shown in two cases still to exist three and five weeks respectively after the injection, and it is probable that it lasts even longer.

419

## Mandelic Acid in Urinary Infections

H. C. GRAM (*Ugeskr Laeg* February 17, 1938, p 172) notes that the widespread enthusiasm for mandelic acid has hitherto been but little tempered by controlled observations with other well-known urinary disinfectants. To make good this omission he carried out controlled tests during 1936 and 1937 with three different urinary disinfectants. In each of three groups he had twenty-seven patients, and the duration of treatment for all three groups was fourteen days. At the beginning and end of this period catheter specimens of urine were taken and were examined both directly and by culture, these laboratory tests were undertaken by persons unfamiliar with the clinical course of the cases. Each patient in the first group received 27 grammes of salol and 81 grammes of calcium chloride in the twenty-four hours, in the second group 127 grammes of hexamethylene tetramine and 89 grammes of ammonium chloride, and in the third group 12 grammes of a palatable preparation of mandelic acid. The recovery rates, as judged by the laboratory reports were 33 per cent and 30 per cent respectively for the first two groups, and 85 per cent for the third group. Judging only by the direct microscopical test, the recovery rates for the three groups were 41, 33, and 93 per cent respectively. A special study was made of the cases of pyelitis of pregnancy, as this is notoriously refractory to treatment with urinary disinfectants. The urine of none of the seven patients with this condition in the first group was sterilized, and the urine of only one of the four patients in the second group was sterilized, whereas this result was achieved in five out of seven cases of pyelitis of pregnancy in the third group. *B. coli* was equally distributed in the three groups, and was numerically the most important of the infecting organisms. As a footnote to this comparison, so strikingly favourable to mandelic acid, the author remarks that in his experience it has given rise to no complications.

420

## Insulin Allergy

H. MALTEN (*Munch med Wschr* February 4, 1938, p 166) points out that insulin allergy is a rare but well-defined clinical entity. It is probably not due to the insulin itself but to the proteins present in the various brands on the market. It manifests itself in local urticaria at the site of injection or in subjective symptoms—for example, headache, lassitude, and symptoms resembling closely those of hypoglycaemia. A dirty skin, one in which a small quantity of alcohol has been used, may produce local symptoms, and must therefore be taken out of consideration. Different brands of insulin then be tried in the hope of finding one which does not provoke an allergic response. Since insulin can be dispensed with in the treatment of diabetes the patient in some cases must be desensitized by the administration of small doses of the toxic agent. The author advocates a vegetarian and salt-free diet as an adjuvant in desensitization. Carbohydrates must be increased and, provided that they are kept in quantity and are adequately compensated by the administration of sufficient insulin, no harm results. He describes a case of severe allergy in a patient moribund through lack of insulin. The condition was cured in six weeks by the treatment outlined.

# Dermatology

## 421 Exfoliative erythrodermia from Milk Tern

S. NEUMARK (*Derm. Wschr.* March 19 1938 p. 51) describes the case of a woman aged 6 who after taking filix mas for tapeworm suffered from pyrexia, vomiting, bloody diarrhoea, oliguria, haematuria, mental psychopathy and a generalized exfoliative dermatitis. After discharge from hospital a month later generalized psoriasis developed. Exfoliative dermatitis after filix mas does not appear to have been noted hitherto although psychosis with mania, and in another case sudden death with symptoms suggesting anaphylactic shock have been reported—in both instances following a second treatment by milk tern for worms. In Neumark's case the previous treatment of this sort—at the age of 12—had been followed by exfoliative erythrodermia with shedding of the hair and nails and (later) psoriasis. He inclines to regard the case as being of an allergic rather than a toxic nature and dependent on idiosyncrasy. Later the administration of one thirtieth of the previous dose induced similar symptoms—a cutaneous application of milk tern extract (or to a less extent of filmaron) led to acute general toxic and cutaneous symptoms. An additional factor may have been reinforcement of the sensitization by the tannin for intense local and general reactions followed intra cutaneous injection of an extract of tannin. No castor oil had been taken in this case. Neumark alludes how ever to recent work casting doubt on the belief that castor oil increases the toxicity of filix mas.

## 422 Porphyrins and Actinic Dermatitis

From the absence of porphyrin in the urine in some patients having light dermatoses E. URBACH (*Klin. Wschr.* February 26 1938 p. 704) was led to examine the faeces and in a single summer he noted seven cases characterized by (1) gross stercoporphyria without haematoporphyrinuria (2) profound pathological modifications of the gastro-intestinal flora (3) hepatopathy and (4) light dermatoses of various kinds including moist dermatitis, chronic eczema conditions resembling lupus erythematosus, chronic pigmentations and pellagra-like dermatoses. Porphyrins disappeared from the faeces when animal poisons were withdrawn from the dietary. Disturbed hepatic function was shown by defective deaminization after the administration of amino acids. The pathological flora consisted in atypical *B. coli*, enterococci and yeasts. Normal bacterial conditions were restored and the dermatoses, actinic sensibility and coproporphyrin disappeared after the administration of living normal *B. coli* strains. Importance was attached not only to this vaccine treatment but also to restoration of the impaired liver function by the administration of liver extract and dextrose together with a diet free from animal protein. The usual treatment in darkness or with masks was adopted in the early stages. Stercoporphyria in combination with light sensitiveness has previously been reported in England by Barber and Riffel and also in hydroa vaccinatorum.

## 423 Eczema

A. STÜHMER (*Med. Welt* February 26 1938 p. 302) stresses the importance of preserving the distinction between seborrhoeic eczema in Unna's sense and true eczema in which the primary efflorescence is always accompanied by vesiculation and there is a combination of cutaneous irritation with cutaneous hypersensitivity which may be congenital or more often acquired. Acute eczema is an epidermal disease to which in the chronic stage is added a vascular dermal reaction. The irritant factor may be external—as in occupational or pruritic eczema and in light warmth or cold hypersensitivity—or internal as in dietetic eczema which is infinitely more common in children. In the former group mycotic and other fungi and frankly bacterial causes especially strepto-

cocci are often overlooked. Stühmer remarks that modern therapy by multiplicity of intravenous injections of vitamins and hormones is doomed to failure if the dermatological diagnosis is incorrect; he believes that reducing and dehydrating treatments are sometimes employed unnecessarily and ineffectively. Local treatment should be in the foreground and in Stühmer's practice is invariably carried out in detail by himself. Usually he begins in acute cases with loose moist applications of 3 per cent boracic lotion or a solution of salicylic acid 0.5 part and resorcin 2.5 parts in 200 parts of distilled water. A day or two later 5 to 5 per cent thigenol paste is applied to be replaced after four to five days by thick coal tar dressings applied for five days. A further paste application follows. Ointments are little used. X-ray therapy is useful at the end but not at the beginning of treatment. The intake of food and fluid should be somewhat reduced. A salt free diet is not helpful but other condiments should be avoided. Stimulation of healthy skin function by natural or artificial sunbaths or by swimming is to be recommended in many cases.

## 424 Virus in Pemphigus Vulgaris

J. WERTH (*Arch. Derm. Syph.* Berlin February 14 1938 p. 382) alludes to recent reports by German and Japanese workers of a filterable virus in pemphigus vulgaris transmissible to rabbits. In his own experiments material from the vesicles was inoculated into the anterior chamber of the eye in rabbits or guinea pigs, panophthalmitis eventually occurring. After several passages from eye to eye the fluid ultra filtrate retained its pathogenicity for rabbits and could be cultured by successive inoculations in the chorion allantois of the hen's egg. From the allantois colonies of extremely minute round corpuscular elements staining by Giemsa or Victoria blue were isolated; they were regarded as the pemphigus virus and were also found in sections of the cornea in the experimental animals. There was evidence in these of establishment of immunity. Animal inoculation of the cerebrospinal fluid (or cerebral extracts) from pemphigus patients was ineffective.

## 425 Traumatic Marginal Alopecia

H. RIBEIRO (*Brazil. med.* December 25 1937 p. 1267) records two illustrative cases in women aged 40 and 47 presenting an alopecia of the scalp similar to that termed frontal luminal alopecia by Sabouraud and marginal traumatic alopecia by Ribeiro. This condition is due to continuous or frequently repeated traction of the hair which gives rise to inflammation of the hair follicles. The condition is particularly common among coloured women who wish to imitate the style of hairdressing adopted by white women.

## 426 Dermatitis Atrophicans Lipoides Diabetica

H. GOTTRON (*Med. Klinik* February 4 and 11 1938 pp. 145 and 190) discusses the pathogenesis of a peculiar dermatitis originally described by Oppenheim as dermatitis atrophicans lipoides diabetica and by Urbach as necrobiosis lipoidica diabetica. The author however prefers to call the disease granuloma necroticans lipophilum or lipoidicum. The affection is the outcome of the disturbed diabetic metabolism and may develop even in the absence of a high blood pressure, the appearance of the skin lesions is often determined by injury. The localization and appearance of the lesions vary but microscopically they are all more or less alike. At a certain stage of the evolution of the lesion there is a deposit of isotropic fats exceptionally of crystallized cholesterol in the necrobiotic areas. The deposit of fats is preceded by the necrobiosis of the cutaneous tissues. The distribution of the fat may be diffuse or in the form of rosettes. It is mostly extracellular, rarely intracellular in the form of minute drops. It may also be deposited in concentric layers around anatomically altered blood vessels. Fat is also found in the dilated lymphatic capillaries. In long standing cases there may also be a deposit of calcium.

## Obstetrics and Gynaecology

### 427 Urethral Prolapse

N E BERRY and H GREENE (*J Urol* February, 1938, p 92) say that prolapse of the urethral mucous membrane through the external urethral meatus is a condition usually referred to gynaecologists. Of the recorded cases 60 per cent occurred in children and 28 per cent in women over 40. The symptoms are itching and burning, and sometimes severe and continuous pain with vesical tenesmus and frequent micturition. On inspection there is a small tumour anterior to the vaginal orifice with a slit in the middle corresponding to the urethral meatus. The colour varies from deep red to blue, and there may be ulceration or gangrene with sloughing of the protruded tissues. The condition should be differentiated from a caruncle, which projects from one side of the meatus, and from a urethral polyp, which is encircled by the orifice. One case that of a girl aged 10, is described. It was treated by circular amputation of the prolapsed mucosa, which was strangulated and almost gangrenous. The fulgurating diathermy knife was used. On the second day there was brisk haemorrhage, which was controlled by an indwelling catheter. This was removed two days later and the urethra healed promptly. Post operative stricture may be prevented by occasional timely dilatation of the urethra.

### 428 Acetonuria and Menstruation

H ISELIN (*Schweiz med Wsch* February 19, 1938, p 175) has noted the presence of acetonuria in a number of women just before and during menstruation. It is not known whether this is a constant occurrence and whether it is due to the action of the pituitary as is probable. The importance of acetonuria at the time of menstruation lies in the associated sensitivity of the liver to toxic agents—for example chloroform. Consequently all operative measures under narcosis should be avoided during the menses.

## Pathology

### 429 Hypovitaminosis C in Tuberculosis

P A DELILLE and G URBAIN (*C R Soc Biol* 1938, 127 522) made observations on children under 16 years of age who were suffering from pulmonary tuberculosis. A dose of ascorbic acid of 10 mg per kilogramme of body weight was given by the mouth. The urine was collected for the next twenty four hours in a flask containing 1 ccm of acetic acid in order to avoid oxidation of the vitamin and the ascorbic acid content was determined by methylene blue titration. Normal children eliminated between 10 and 30 per cent of the ingested ascorbic acid. Tuberculous children eliminated none. Ascorbic acid had in fact to be given for some days to these children before they began to excrete it in the urine. Tuberculous children who had recovered under sanatorium treatment had a normal ascorbic acid excretion. It seems clear therefore that in pulmonary tuberculosis in childhood there is an abnormally high consumption by the tissues of ascorbic acid.

### 430 Synovial Fluid in Gonococcal Arthritis

W W SINK and C S KEEFER (*J clin Invest* January, 1938, p 17) have investigated the bactericidal power of synovial fluid and blood in cases of gonococcal and non-gonococcal arthritis. In non-gonococcal cases the fluid was not gonococcidal owing to the absence of specific antibodies and not to the absence of complement. In gonococcal cases when the fluid was infected with gonococci antibodies were absent although they might be

present in the blood, when the fluid was sterile anti-bodies were present in it as well as in the blood, and often in the same concentration. Actively gonococcidal fluids lost their gonococcidal power when heated to 56° C for thirty minutes, their activity could not be restored by adding immune serum, but it was restored on adding complement. Inactive fluids could be made gonococcidal by adding immune serum, but if they had been heated addition of complement was necessary as well. The gonococcidal power of the fluids depended therefore on the presence of both specific antibodies and complement. Complement was found to be present in about the same concentration as in the blood in all three types of fluid tested. When the fluid was infected its gonococcidal power was less than that of the blood, when the fluid was sterile its gonococcidal power was equal to or only slightly less than that of the blood.

### 431 Alcohol Determination at Necropsy

G GULDBERG (*Norsk Mag Laegevidensk*, March, 1938, p 241) has carried out alcohol determinations at necropsies for medico-legal purposes on thirty five men and five women in Oslo between 1931 and 1937, he used Widmark's technique. In seven cases separate examinations were made of the blood, urine, and contents of the stomach. It was found that the concentration of alcohol in the stomach varied widely from 2.67 to 41 parts per thousand. In as many as seven cases the primary cause of death was alcohol poisoning with ethyl alcohol in five cases and a mixture of ethyl alcohol with methylated spirits in two. In most cases alcohol had played only a secondary or contributory part, death being usually traumatic. In one case the examination of the urine in the bladder for alcohol was carried out seven weeks after death, and yet the author succeeded in demonstrating in the urine a reducing body the quantity of which corresponded to 3.21 per thousand of ethyl alcohol. This finding was of considerable medico-legal importance and to the advantage of the motor driver held responsible for the death of the person examined after exhumation. For the evidence to the effect that this person was intoxicated at the time of the accident found confirmation at the post mortem examination. As alcohol present in the stomach at the time of a fatal accident may diffuse through its walls after death, the author recommends taking samples of blood for alcohol determination from some part of the body remote from the stomach. He is very sceptical as to the value of a smell of alcohol as a guide to the alcohol content of a dead body. For a smell of alcohol under these circumstances will depend on many different factors, such as the temperature of the body, other odours proceeding from it, and the nature of the alcohol assumed.

### 432 Tuberculous Spondylitis

A DI NEPI (*Arch ital Anat Istol patol* February, 1938, p 269) describes the following changes encountered in the intervertebral disk at necropsies on ten cases of tuberculous spondylitis. In the first stage there were degenerative changes in the disk, consisting in elongation of cartilage cells in the lamina with fibrosis of the intervertebral substance and the appearance of large irregular areas of degeneration with abnormal coloration of the substance, or of small round amorphous areas of calcification. These zones of calcification were also found in the annulus fibrosus and nucleus pulposus with an increase in the number of cartilaginous cells. In later stage specific changes were found in the disk consisting first of erosions of the lamina with perivascular buds and inflammatory cells in the pulp filling up of the cavity of the nucleus with fibrous tissue and lastly invasion of the whole disk by a specific process with a non-specific reaction of connective tissue proliferation interspersed with and necrosis of the granulation tissue.

# Pure, active, comfortable and inexpensive

The chemistry underlying liver therapy  
is ever changing .....

An increasing tendency is shown to claim a very high purity and remarkable hæmopoietic potency for injectable fractions of liver

Independent chemical research in stringent conditions of clinical test have maintained the place of Organon's PERNAEMON FORTE in this field

PERNAEMON FORTE now a clear solution, provides a medium for the therapy of Pernicious Anæmia as pure as active as comfortable and as inexpensive as any available.

# Modern Iron Therapy

Iron 'Jelloids' are an elegant and reliable means of administering the protocarbonate of iron. The preparation has none of the disadvantages of Pil Blaud. The iron content remains fresh and unoxidized indefinitely, and

injury to teeth is avoided. The Jelloids are highly effective in the treatment of achlorhydric anaemia and indeed in all the simple anaemias in which massive iron therapy is indicated.

## Iron Jelloids

### TOXAEMIAS OF PREGNANCY

Because of its general alkalinizing eliminative and antiseptic action SALVITAE tends to obviate fermentative and putrefactive changes in the intestinal tract—so important in the treatment of pregnant states. SALVITAE helps to dissipate headaches, vertigo, insomnia, etc., which so often presage an impending uremia.

# SALVITAE

It serves to prevent or clear up oedema, activates safely the sluggish kidneys and relieves dyspnoea and cardiac embarrassment. SALVITAE given to a woman throughout the gravid state practically insures her against toxicæmic or acidotic disaster.

## The Court of LAST APPEAL

The electrocardiograph serves such an important purpose in the general practice of medicine that every physician has need for it. In the identification of disturbances of mechanism of the heart beat it constitutes the court of last appeal. It gives vital information regarding all cardiac arrhythmias.

Simplified inexpensive dependable electrocardiography has been made available to the average physician with the advent of Victor's new light weight, low priced instrument which can be used with equal satisfaction in

the consulting room or at the bedside. It is sturdy yet portable, it is extremely accurate and requires no complicated manipulation to produce a heart record that is of true diagnostic value.

Without incurring any obligation arrange to make an electrocardiogram yourself. It is a surprisingly simple procedure and interesting. Learn at the same time what a valuable adjunct it would be to your other diagnostic equipment, valuable as an investment too. Simply sign and post the convenient coupon now

### WITHOUT OBLIGATION

# ROYAL NAVAL MEDICAL SERVICE.

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in July, 1938

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years, which if desired is usually extended to five years at the discretion of the Admiralty.

At the end of three years' service, officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000.

At the end of five years' Short Service permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Full opportunities exist for transfer to the permanent list, and periods of unemployed or half pay are very rare. The assistance of private income is not necessary for the purpose of supplementing official pay and allowances.

Opportunities are available for officers on the permanent list for post-graduate study, to specialise, to take higher examinations and to obtain further qualifications.

Naval Medical Officers are included in the Scheme for Marriage Allowance under the same conditions as for other Naval Officers.

Copies of the regulations for entry and conditions of Service, including rates of pay, allowances and retired pay may be obtained from the Medical Director-General of the Navy, Admiralty, S W 1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than 31st May, 1938

## MEDICAL STAFF — PRISON SERVICE (ENGLAND AND WALES)

Applications are invited for the post of male Medical Officer Class II in the above Service. Commencing salary £525 per annum rising by annual increments to £800 per annum with unfurnished house (free of rates) or an allowance in lieu. The post is pensionable.

Candidates must be fully qualified and registered. Preference will be given to those who have held House appointments, have had experience in mental diseases and psychological methods and are between the ages of 25 and 35 years. The commencing salary for those holding the Diploma of Psychological Medicine will be £575 per annum.

Of the whole time Prison Medical Officers sixteen are Class II and twelve are Class I. Promotions from Class II to the rank of Medical Officer Class I on a salary scale of £800 per annum rising to £1,000 per annum with unfurnished house (free of rates) or an allowance in lieu are made as vacancies occur. Three of the senior Medical Officers receive an additional allowance of £50 per annum and at certain Prisons Medical Officers receive fees for giving evidence in the Criminal Courts.

Forms of application can be obtained from the Secretary (Staff Branch) Prison Commission Home Office, London S W 1.

## CITY OF SALFORD PUBLIC HEALTH DEPARTMENT

Applications are invited from fully qualified Male Medical Practitioners for the post of Assistant Medical Officer (whole time) in the Venereal Diseases Treatment Centre at which the yearly attendances and new cases treated average 95,000 and 2,000 respectively. The salary will be £500 rising by annual increments of £25 to £700 per annum. Applicants must have had previous experience in the treatment of Venereal Diseases and must possess a certificate of attendance and instruction at a Venereal Diseases Treatment Centre as specified in the Local Government (Qualifications of Medical Officers etc.) Regulations 1929.

Forms of application etc. may be obtained from the Medical Officer of Health 143 Regent Road Salford 5 Lines to whom they should be returned accompanied by copies of not more than three recent testimonials not later than Saturday May 28th 1938.

H. H. TOMSON Town Clerk

## CITY OF COVENTRY ASSISTANT SCHOOL MEDICAL OFFICER AND ASSISTANT MEDICAL OFFICER OF HEALTH

The Coventry City Council invite applications from Registered Medical Practitioners under 40 years of age for the post of Assistant School Medical Officer (male) in connection with the medical inspection etc. of schoolchildren. When not engaged in school work the officer will be required to assist in the general work of the Public Health Department.

Applicants must possess a Diploma in Public Health and preference will be given to those with appropriate previous experience.

The salary will be £500 rising by annual increments of £25 to a maximum of £700 per annum.

The post is designated under the Local Government and Other Officers Superannuation Act 1922 as intended in regard to gratuities to widows by the Coventry Corporation Act 1936 and the successful applicant will be required to pass a medical examination as to fitness and to contribute to the superannuation fund. The successful applicant will also be required to contribute to the Coventry Staff Widows and Orphans Pension Fund.

Applications together with copies of three recent testimonials must be made on the prescribed form (which may be obtained from the undersigned) and must be delivered not later than May 25th 1938.

FREDERICK SMITH Town Clerk

The Council House Coventry  
May 10th 1938

## CITY OF BATH DEPUTY MEDICAL OFFICER OF HEALTH AND DEPUTY SCHOOL MEDICAL OFFICER

Applications are invited for the appointment of Deputy Medical Officer of Health and Deputy School Medical Officer at a salary of £700 per annum rising by two annual increments of £50 to £800 per annum.

Candidates must have had experience in the duties involved and must possess the Diploma in Public Health. Age limit 45 years.

The post is designated one for superannuation purposes and the successful candidate will be required to pass a medical examination.

Further particulars and form of application may be obtained from the undersigned to whom applications must be delivered not later than May 25th 1938.

Guildhall Bath  
May 9th 1938

J. BASIL OGDEN  
Town Clerk

# Medical Men supervised the design of the Linia Belt

The Belt for correction of Ptosis, Obesity, Faulty Posture and for post-operation wear

It was on the advice of medical men that the Linia Belt was evolved, frequent tests by doctors were carried out before it was made available for sale. That is why it is the recognised belt for men's wear.

Made to measure for every case, the Linia Belt is prescribed for obesity, for various ptotic conditions, for post-operation wear, for wear by the older man during golf and so on. The front is of thin, non-elastic tinct, the back of strong elastic. It is fully adjustable by slide buckles.

## YOU CAN ORDER BY POST

## For those Cases where SPECIALISED FOOTWEAR is Indicated...

For normal and abnormal foot cases Hardy's MASTAFIT footwear supplies a much needed service. No longer is it necessary to make the bulk of such shoes to measure for MASTAFIT shoes are stocked in several different foot formations on the principle that every foot type needs its own particular shoe. Medical men are invited to call and test the system in daily operation. A parcel of shoes (please state size) and booklet will be gladly sent for inspection on application.

# When your patient needs a **HEARING AID-**

the obvious move is to send him to a firm offering facilities for testing ALL TYPES of reliable aids, and who will, at the same time, consider it their personal obligation to give both doctor and patient complete satisfaction

Allen & Hanburys' Acoustic Department has a reputation for giving every consideration to the personal problems of deaf patients when some form of artificial aid becomes necessary. Audiometers tests are made, a home trial arranged, and a full report submitted to the doctor concerned. Once the aid has been supplied, contact with the patient is maintained until all the small difficulties experienced in the early stages of use are overcome. Provision is also made for adjustments to meet any change in aural conditions at a later date.

In short, a comprehensive after-service is available to each patient, ensuring that not only his immediate but also his future needs in relation to a hearing aid are safeguarded in an ethical manner.

# FOOT COMFORT

By wearing  
**'APTERNA' HEEL-LESS SHOES**

These shoes are designed in the common sense knowledge that the majority of foot troubles are due in large measure to faulty footwear which aggravates the trouble and does not permit the natural exercise and freedom which is essential to foot health.

*Charles H. Baber*

LANGHAM HOUSE, UPPER REGENT ST, W 1

Any of the common foot ailments mentioned in the above diagram can be successfully prevented and relieved by wearing the corrective series of Apterina Heel-less shoes.

Apterina Shoes are available for men, women and children.

## THROMBIN-COAGULANT-MAW DRESSINGS FOR THE MAJOR OPERATION OR THE MINOR CUT

Some time ago we announced the production of Thrombin Coagulant-Maw, a preparation of remarkable efficiency for clotting blood.

We now offer a range of Surgical Dressings known as Thrombin-Coagulant Maw Dressings to which this preparation has been applied with such regard for the scientific principles concerned both chemical and physiological that we venture to suggest a new method of treatment has been found.

THE PHYSIOLOGICALLY CORRECT FIBROGEN

Whenever a wound is accessible to the application of a Dressing TCM Dressings will be found of great value in all cases requiring hæmorrhage control. They are very reasonable in price and represent a true economy of your own time and money whenever hæmorrhage has to be treated.

### COLLOIDAL ASSIMILABLE PALATABLE

Ovoferrin Brand Colloidal Iron Tonic, the palatable blood builder, is strength-giving, odourless, non-astringent. It is iron in its most minute, most useful colloidal subdivision. Ovoferrin does not constipate, it does not affect the teeth or stomach, rather, it stimulates the jaded appetite and often aids in intestinal peristalsis. Many physicians have found it to be the only preparation simple, agreeable and effective enough for long term iron feeding. Ovoferrin contains no flavouring or sugar, it is economical to use and an excellent vehicle. Write for free professional sample.

Campho Sulphonate of sparteine	60 grains
Campho Sulphonate of ephedrine	5
Extract of boldo	100
Extract of crataegus	100
Extract of salvia	100
Tincture of marrubium	100
Glycine extract of thyroid (it equals 1 of fresh gland)	0.10
Valerian	100
Hexamethylene tetramine	100
Excipient q.s.	ad 1,000 grains

PRICE 7/6 per 4 oz. bottle  
Sample and Literature on request

*Serenol* is a sedative with action on the centres of the nervous vegetative system, sympathetic and parasympathetic, and on the cortical centres. Recent knowledge has shown the interaction of nervous vegetative system and endocrine system and on this knowledge *SERENOL* is based. It is thus a biological, not a symptomatic, sedative, and unlike many other sedatives has not a direct depressant action on the cortical cerebral centres.

*Serenol* is indicated in conditions of anxiety and general instability, insomnia, hyperthyroidism, hyperadrenalism (as in neurocirculatory asthenia, effort syndrome), the so-called nervous palpitations of the heart, etc.

*Serenol* is given in the following dosage: For mild cases one to two dessertspoonfuls on retiring. For more severe cases one dessertspoonful 3 to 4 times a day, one dessertspoonful 4 or 5 times a day and two dessertspoonfuls on retiring.

*Serenol*, being a biological sedative containing no habit-forming substances, is no habit-forming.

## Prepared for the mouth and throat

'Dettolin' is specially made to kill quickly the micro-organisms concerned in affections of the mouth and throat. It contains, among other ingredients, the active germicidal principle of 'Dettol'—the modern antiseptic. For all its high germicidal efficiency, 'Dettolin' is soothing and gentle on delicate tissue. It has the added advantage of being distinctly pleasant to use, an important factor when frequent and regular gargling is prescribed.

'Dettolin' is obtainable from Chemists and Medical Dispensaries.  
Price 9d. and 1/3. Sample, and full information on request.

# ASCORBIC ACID B.D.H.

(VITAMIN C)

A suboptimal intake of Vitamin C may result in the onset of such subscorbutic symptoms as certain types of secondary anæmias, defective deposition of calcium in bones and teeth, disturbed water metabolism and, in premature or under-developed infants, a delay in growth

A more marked deficiency of the vitamin may result in the onset of various forms of scurvy including Barlow's disease as well as cataract and possibly reduced resistance to infection

Such deficiency may result from low intake or from increased utilisation, as during febrile conditions or reduced absorption in hypochlorhydric conditions. The existence of a state of subsaturation with Vitamin C,

with consequent risk of onset of symptoms of deficiency, may be detected following the administration of a test dose (70 mg per stone body weight)

In prophylaxis 12.5 to 50 mg (250 to 1000 international units) of Ascorbic Acid B D H (Vitamin C) should be given daily

In treatment doses of 150 to 250 mg (3000 to 5000 international units) should be given daily, and in febrile conditions similar doses should be given to meet the increased demands of body metabolism

Ascorbic Acid B D H is generally, and most conveniently, given orally in the form of tablets, but in cases of gastric dysfunction and hypochlorhydria it is injected intravenously in the form of a solution

# ALASIL

## Better Salicylate Therapy

**W**HATEVER be the season of the year there is a wide sphere of utility for Alasil the improved form of salicylate medication.

Alasil is a very definite advance on ordinary compound of salicylic or acetyl salicylic acid both in therapeutic efficiency and in freedom from the risk of unpleasant gastro-intestinal sequelae. This high tolerability is due to the fact that Alasil is composed of calcium acetyl salicylate—the least irritating of the salicylate compounds—and Alocol (Colloidal Hydroxide of Aluminium) a powerful gastric sedative and antacid.

A careful series of experimental tests has shown that Alasil is more completely absorbed than ordinary salicylate compounds and that it is practically free from the risk of irritating the gastric mucosa in the stomach.

Wide clinical experience anticipated these findings by demonstrating that

Alasil can be pushed or prolonged to a much greater extent than ordinary salicylate compound and that it can be given with safety to children, aged, and patients with finely balanced digestive capacities. An antacid and purgative and sedative of established value.

*A major operation in progress in the operating theatre of a London Hospital*

## DEGREES OF PROTECTION . . . .

THE most elaborate precautions against every possible chance of germ infection are of course essential in the operating theatre. It would be ridiculous, however, to expect anything approaching this meticulous attention to antiseptic cleanliness in everyday hygiene and in the home treatment of superficial wounds.

The general public is nevertheless beginning to realise the importance of germ-free cleanliness. Hygienic standards to-day are higher than they have ever been. It is generally agreed by medical men that although regular use of antiseptics is not desirable or really necessary for ordinary toilet purposes, the use of a reliable antiseptic soap can play a very valuable part in the prevention of infectious disease. Face and hands are continually exposed to infectious germs, and require washing with Wright's Coal Tar Soap.

Wright's has substantial antiseptic and antipruritic qualities. For over 70 years it has enjoyed the confidence of the medical

profession, and to-day more doctors use Wright's than any other brand of toilet soap. Wright's Coal Tar Soap is prepared from materials selected after stringent tests. It is the only soap in the world to contain 'liquor carbonis detergens' (Wright's), the valuable dermatological therapeutic recommended by skin specialists the world over. In surgeries, hospitals, nursing homes and private households Wright's meets all the requirements of modern everyday hygiene. You can use it and recommend it to your patients with complete confidence.

**WRIGHT'S**

Wright, Layman & Umney Ltd., 44, 50 Southwark Street, S.E. 1

# Disease-emaciation

"EVERY medical practitioner knows how difficult it is to nourish a patient suffering from disease. Do we not all recognise the fact that the starving tissues are fed not only by food swallowed by the patient, but by the amount of nutriment absorbed by the gastric and intestinal mucous membrane? If we could ensure the absorption of nutriment into the blood the problem of nutrition in disease would be reduced to a matter of mere chemistry and mechanical feeding. Judging from clinical results Sanatogen appears in many cases to possess some power of readily absorbing nutriment from the richest foodstuff represents so much nutriment in the 'cells' and intestines. My own experience of Sanatogen in the treatment of emaciated—ten or twelve months old—are often reduced to a mere skeleton—feeding, and it improves general condition of the child, and eventually leads to a normal weight."

NUTRITION IN WASTING DISEASES OF CHILDREN AND ADULTS  
(Lancet, 1937, 1, 1000)

"THIS condition will result from imperfect diet or absorption of which may follow stomatitis, pyloric stenosis, diphtheria of the pharynx, tuberculous or syphilitic is not infrequently associated with improper feeding. In such cases are not well tolerated but the contrast is true in reference to food. The use of Sanatogen, in these cases, proved to be the best method of feeding. I am encouraged to try it in other cases of intestinal weakness and have had a most encouraging results in a number of patients suffering from this condition. It is quite apparent that 'Sanatogen' has considerable power in influencing nutrition."

'INFANTILE ATROPHY'  
(Practitioner, 1937, 1, 1000)

"I HAVE before me the records of forty cases fed with Sanatogen. They show what was obvious to myself and the nurses when watching the cases—their babies wasted less during the acute stage and picked up more rapidly during the convalescent stage than patients who did not have Sanatogen. This fact indeed was soon recognised by the ward sister without my having in any way drawn her attention to it. I am firmly convinced that it is a most valuable food for the emaciated patient."

THE TREATMENT OF TYPHOID FEVER  
(Lancet, 1937, 1, 1000)

5 to 10 c.c.s.  
per 3 to 199

DOSEAGE: For children and adults who are unable to take food, 5 to 10 c.c.s. of Sanatogen should be given 4 or 5 times a day, and gradually increased as the patient improves.

# Vitamin Concentrate or Natural Food?

The normal daily dosage of Bemax, i.e.,  $\frac{1}{2}$ -ounce, provides 200 International units of Vitamin B<sub>1</sub>, which is from four to ten times as much as the recommended daily dosage of certain Vitamin B<sub>1</sub> "concentrates" advertised to the medical profession. If a higher intake is required, it is possible to supply as much as 600 to 800 units of Vitamin B<sub>1</sub> daily by the administration of three to four tablespoonfuls of Bemax, and thus in an entirely natural form at only a fraction of the cost of concentrates.

The Vitamin B<sub>1</sub> potency of Bemax is assured by biological assay of every day's output, and is from 12-15 International Units per gramme, about 400 units per ounce.

## BEMAX

A unique natural source of accessory nutritional factors

Vitamin B <sub>1</sub> —400 International Units per ounce	Vitamin E—the richest natural source
Vitamin B <sub>2</sub> —Flavin present 30—rich supply	Phosphorus—330 mg. per ounce;
Vitamin A—250 International Units (as Carotene)	Magnesium—99 mg. per ounce
	Iron — 3 mg. per ounce
	Copper — 0.45 mg. per ounce.

## SEX HORMONE PREPARATIONS

*in the Treatment of Threatened Abortion**also of Habitual and Missed Abortion*

## THREATENED ABORTION

In the treatment of threatened abortion direct therapy with the luteal hormone Progestin B D H is advocated on account of its inhibitory action on the myometrium the expulsive movements of the uterus thus being allayed. The usual dosage is 2 I U Progestin B D H daily from the onset of symptoms until two or three days after pain and bleeding have ceased. Cases in which the danger of abortion is imminent may be given greatly-increased dosage with absolute safety.

## HABITUAL ABORTION

For this condition the use of Gonin is recommended in order to stimulate activity of the corpus luteum.

Doses of 100 R U twice weekly should be administered from the time at which pregnancy is first established until the thirty second week. The times at which the menstrual flow would normally have appeared had it not been suppressed are usually regarded as being periods of special danger and the injection about this time may for safety be increased to one of 500 R U.

## MISSED ABORTION

In order to cause evacuation of the uterus in cases of missed abortion the oestrogenic hormone is employed with the object of stimulating uterine motility.

Injectations of Oestroform 50 000 I B U are administered every eight hours until evacuation of the uterus occurs.

# Laxatives for Children

The choice of laxatives for children is governed by many exacting considerations. To aid the Physician in assessing the merits of Andrews Liver Salt, its main characteristics are briefly listed below

- 1 The dosage is easily adjusted according to age
- 2 It is pleasant-tasting. Children accept it readily
- 3 The taking of Andrews is not followed by the griping or other pains that often lead to psychological revulsion against the more drastic purgatives. Its laxative action is extremely mild and is due to the presence of magnesium sulphate and other salts, which increase the fluid content of the bowel by Osmotic action and so lead to painless, easy evacuation
- 4 Andrews has a soothing effect on the stomach and a physical cleansing action on the stomach walls which breaks up any unhealthy coating of mucous. It is also useful as a gastric sedative in the bilious attacks to which many children are prone
- 5 The action of Andrews is not limited to the elimination of waste, it also corrects excess acidity, stimulates the flow of bile and generally aids the digestive system
- 6 Andrews creates no dependence on artificial aid, but can be discontinued when the need for it ceases

## DOSAGE FOR CHILDREN

*From two years of age, it is safe to start with  
½ teaspoonful and to increase the dose as necessary  
for older children*

AN IMPORTANT ADVANCE  
IN  
*Menstrual Hygiene*

TAMPAX

SANITARY PROTECTION WORN INTERNALLY

Every physician has frequent occasion to use vaginal tampons in the therapy of cervix or vagina. He knows that this method safely, comfortably and effectively absorbs discharges at the site. It was this knowledge which originally prompted a physician to design Tampax. To day, in its perfected form, Tampax is available for purposes of sanitary protection.

Immediately upon emergence from the cervical canal the menstrual fluids are taken up by the highly absorbent, long-fibred surgical cotton of which Tampax is composed. Each tampon has an absorption capacity of 1 to 1½ ounces. As it absorbs the fluids, the tampon opens gently to a soft mass, comfortably adapting itself to the size and form of the vaginal walls. The tampon is contained in the vaginal way from contact with the urethra and minimises contamination

*Expanded Tampax 11541000  
its adaptation to the female  
and its safe maintenance*

from this source. Infections of rectal origin are likewise avoided.

A patented sealed applicator enables the user to insert Tampax in the proper position without contact with the hands. It can be removed in an instant by means of a cord drawn through the cotton by a patented stitching process which makes

disintegration impossible.

Dispensing thus with sanitary towels, Tampax provides relief from physical and mental discomfort. It confers freedom and peace of mind. Physicians may recommend the use of Tampax to the vast majority of their women patients in the fullest confidence.

We will be glad to send to doctor a full-size package of Tampax together with a folder giving more complete detail on request to Tampax Ltd 10, Bolton Street, London W 1.

# ENO'S 'FRUIT SALT' CONTAINS NO SUGAR

Nearly all effervescent salines contain a high proportion of one or both of the mineral sulphates—Glauber's and Epsom salts. So nauseous are these ingredients that, in order to disguise the taste, they are generally mixed with an equal amount of sugar. Hence, such salines are rightly forbidden to all who suffer from diabetes or from less serious forms of glucose-catabolic failure.

Eno's 'Fruit Salt' contains no trace of sulphate of soda or of sulphate of magnesia, and **is entirely free from sugar in any form**. It is a carefully prepared, unadulterated combination of fruit-acids with alkalis. It owes its pleasant effect on the palate to the even solubility of its granules and to its sparkling effervescence when dropped into water.

Eno is a very gentle, physiologically sound, laxative, its aperient action depending on the principle of osmotic diffusion, whereby there is retained in the alimentary canal a sufficiency of fluid to soften the unabsorbed food

residues, and to impart the requisite bulk, both these factors being essential conditions towards assisting the peristaltic waves to compass easy, regular and complete defaecation.

It has also been established in the course of many experiments, performed by a biochemist of international repute, that **Eno is an effective systemic alkalizer**. It has been shown that **one teaspoonful** (i.e., one ordinary dose) of 'Fruit Salt' is equal, in systemic alkalizing value, to eight ounces of good and fresh orange juice.

In numerous cases of diabetes mellitus and other manifestations of imperfect oxidation of the hexoses, whenever a safe laxative with systemic alkalizing properties is indicated—and this is very often the case—Eno's 'Fruit Salt' is a pre-eminently suitable preparation.

## SOME RECENT ADVANCES IN MEDICAL DIAGNOSIS AND TREATMENT\*

By

A. H. DOUTHWAITE M.D. F.R.C.P.

Physician to Guy's Hospital

Medicine has made such gigantic strides in the last few years that to cover the field would be a task beyond my powers. I shall limit myself to those recent advances with which I am chiefly familiar. Most of these relate to the digestive tract.

### Sialography

The radiographic demonstration of the ducts of the parotid and submaxillary glands has been made possible by the injection into them of substances opaque to x-rays. Payne (1931) described in detail the introduction of lipiodol into the parotid duct. By this means the outline of the main duct and its branches can be demonstrated and, when infection occurs various abnormalities such as spherical dilatation comparable to that seen in bronchiectasis of the lung can be demonstrated. The same writer (1933), describing nineteen cases of *recurrent pyogenic parotitis* fully investigated by examination of the saliva and also by sialography summarizes the symptoms and signs of this by no means uncommon disease. It usually starts with a feeling of fullness in the region of one parotid and then slight swelling. Attacks may be initiated by a meal. The gland gradually enlarges reaching its maximum within a few hours up to twenty-four and subsides over a course of several weeks. During subsidence a foul taste may be experienced and examination may reveal mucopus oozing from the duct. After a period of relief the whole process is repeated. It is interesting to note that the ratio of females to males is 8 to 1. So far as physical signs are concerned the gland is easily palpable not uncommonly tender and with acute exacerbation of the disease fever, increase of swelling and well marked tenderness are present. The saliva instead of being clear contains numerous flakes consisting of shreds of mucus with pus cells, epithelial cells and micro organisms. I have notes of seven patients whom I have seen with this disease and five of them have apparently recovered completely as the result of massage to the parotid directed especially along the line of the duct and also diathermy. In one case of submaxillary gland infection its removal resulted in entire disappearance of symptoms. In the submaxillary gland case and three of my parotid patients the outstanding symptom was in point of fact that of *soreness of the tongue* and owing to the great frequency with which one meets this

most troublesome symptom in practice the possibility of a chronic infection of one or other of the salivary glands should certainly be borne in mind.

### Gastric and Peptic Ulcer

One cannot obtain a clear idea of the advances made in the diagnosis and treatment of these conditions without briefly reviewing the last twenty years or even more. It was Mowbray who was responsible for describing the symptoms of duodenal ulcer and placing that condition on the medical map as a diagnosable entity. In 1921 Bennett and Ryle published the result of their investigations of a hundred healthy students by means of a fractional test meal, and thus applied a further stimulus to gastro-enterology. They showed that 20 per cent possessed a degree of free acidity which fell outside the mean curve. Of this 20 per cent half were hyperchlorhydric and half were hypochlorhydric or achlorhydric. It was about this time that they and other workers popularized the alkaline treatment of gastric and duodenal ulcers. MacCallan, Jones and Fildes (1928) wrote on the cure of gastric and duodenal ulcers by intensive alkaline treatment. They referred to the already well known action of soluble alkalis, rest and diet would cause a disappearance of symptoms and produced various radiographs showing the disappearance of ulcer craters. The investigations of these patients were not, however, repeated after a long enough interval to justify the assumption that they were cured.

We now know that a great number of methods of treatment will result in the apparent cure of an ulcer if judged purely by x-ray appearances. I have produced equally striking effects with histidine in patients who have had no other treatment but am quite satisfied that in spite of the relief of symptoms the ulcers were not cured. This drug which has been used largely in the form of a preparation called *larostudin* is injected intramuscularly daily for fifteen to twenty doses. Numerous and conflicting reports have appeared as to its value. The general opinion of critical observers is that it seems to have some effect in aiding the healing of ulcers but it is not permanent and certainly the preparation cannot replace the more orthodox methods of therapy. I began to doubt its efficacy when I followed up hundreds of treated patients for a few weeks subsequent to the discontinuation of treatment. In every case a relapse was not caused not only from recurrence of symptoms but also from x-ray

\* A British Medical Association Lecture delivered before the Lincoln Division March 10 1938.

appearances within five weeks. No doubt the mere fact of relapse is a strong point in favour of the histidine having done some good, but, on the other hand, it is highly improbable that anything approaching healing could have been produced with such an early return of all the signs and symptoms. There is no evidence that ulceration in the human being is due to a deficiency of histidine, and there seems, in point of fact, no convincing experimental work to justify its use. If a series of patients are treated with an intensive alkali and dietetic regime and compared with those treated with histidine it will be found that there is very little difference in the immediate recovery percentage. On the other hand, the histidine treated patients relapse more readily and far more rapidly than those treated by diet and alkali. Gastroscopy has already taught us that large craters as seen by x rays seldom seem so deep when observed by direct vision. The apparent depth is produced not only by swelling of the mucosa but by contraction of the underlying muscularis.

### Associations of Gastro-intestinal Disease

The remarkable discoveries of Minot and Murphy relative to the treatment of pernicious anaemia, and the more recent work of Castle in explaining the association of achylia with this hitherto fatal disease and with sub-acute combined degeneration of the cord, have given a tremendous forward impulse to the study of gastro-intestinal disease and its relation to more remote systems of the body. I drew attention (Douthwaite, 1936) to an interesting group of hitherto unexplained cases of polyneuritis sometimes of extreme severity, all of which appeared to be associated with disease of the stomach leading to achlorhydria or achylia, and termed these gastrogenous polyneuritis. In view of Castle's recent work it may well be that they are actually examples of European beriberi for it has been shown that in conditions of gastritis and achylia the absorption of vitamin B<sub>1</sub> may be deficient and that an adequate supply of this substance is capable of curing certain types of neuritis, especially alcoholic neuritis, even though the original aggravating factor is still operative.

Fiber (1927) preached unheeded for many years the doctrine of chronic gastritis. He studied stomachs preserved by the injection of 10 per cent formalin solution through the abdominal wall into the peritoneal cavity and into the stomach, and, following that investigation, he advanced the study of gastric pathology by the recognition of chronic gastritis and also of the acute variety. Whether one has to assume that all cases of achylia are the result of chronic gastritis is to my mind quite another matter. This has been accepted as a teaching during the last few years on incomplete evidence, for although it is clear that chronic gastritis might well be expected to produce atrophy of the mucosa in time it is by no means certain that all conditions in which gastric atrophy is present have been preceded by an inflammatory state—in short, by gastritis. One must be cautious before jumping to this conclusion particularly when it is borne in mind that the incidence of achlorhydria and achylia rises steadily with age. It seems on the face of it unlikely that an inflammatory condition of the stomach would attack the populace with such regularity. On the other hand, it is understandable. The point is of importance because it Hurst's view is correct that gastritis is the precursor of achylia and gastritis always precedes the

development of carcinoma of the stomach, except in ulcer cancer, it should be possible materially to reduce the incidence of stomach cancer. If on the other hand, achylia is frequently not the result of inflammatory changes, the whole supposed association between achylia, gastritis, and carcinoma becomes at once subject to considerable doubt. Morley (1937) quotes Robertson's and Wilkinson's cases of cancer of the stomach where test meals taken at intervals have shown the presence of a carcinoma and a free acidity which has steadily diminished. This would suggest that the cancer was responsible for the fall of acid. The most that can be said at present is that, although on theoretical grounds it is probable that the gastritis-cancer sequence is true in a proportion of cases, it must not be regarded as an invariable association, even apart from those cases of cancer which do sometimes arise in chronic gastric ulcer.

### Non-ulcerative Haematemesis and Melaena

In using the term "non-ulcerative" I mean to imply that the cases about to be described are those in which profuse haemorrhage has occurred and shown itself either as melaena or as haematemesis, or both, and in which there has been no preceding history of ulcer and where the most careful investigations have completely failed to reveal the presence of an ulcer after the haemorrhage. Furthermore, the subsequent history of these patients has been quite unlike that generally associated with peptic ulcer.

My attention was first drawn to the possibility of severe haemorrhage occurring in the absence of a readily demonstrable disease in the stomach or duodenum by a patient under my care at Guy's Hospital who had been twice admitted on account of recurrent severe haematemesis. He gave no history of indigestion. Melaena persisted for two or three days only and then cleared up. Several x-ray examinations revealed no disease. A fractional test meal showed achlorhydria and a great excess of mucus in every specimen. The case was presumably one of gastritis. With rest in bed, a non-irritant diet and gastric lavage he rapidly improved. A further test meal revealed a return of free hydrochloric acid and no excess of mucus. There has been no recurrence of symptoms after five years.

A man aged 50 was seen by me three years ago on account of severe haematemesis and melaena again with no preceding history of indigestion. Physical examination was negative except for haemoglobin of 52 per cent and heavily infected teeth. He was treated with soft diet and rest in bed, but had a further severe melaena. His doctor then called in a surgeon who performed a laparotomy and found no abnormality. The patient recovered in spite of this. A test meal revealed exactly the same state of affairs as in my previous case.

A third man, 60 years old was under my care in hospital with recurrent small haematemeses but no pain. A fractional test meal again showed a picture of severe gastritis and absence of free hydrochloric acid and blood in every specimen. In fact it looked very much like the test meal of a carcinoma of the stomach. Repeated x-ray examinations were negative. Stomach washouts were heavily tinged with blood for four or five weeks but ultimately complete recovery took place.

The next three patients were those with hyperchlorhydria. In one there was a history suggesting a duodenal ulcer, but this was not demonstrated by the most careful and repeated x-ray investigations and the profuse melaena for which he came in cleared up in two days. The other two patients are of considerable interest since both of them were doctors and reliable witnesses. The first consulted me because he had noticed black stools and had felt giddy. He said that he had been perfectly well until a few hours after being at a cocktail party where he had had only one cocktail but had eaten a large number of salted almonds. His theory was that these had scratched his mucosa. Investigation in a nursing home revealed the hyperchlorhydria so common in doctors. A x-ray

examination four days after the melanin showed a normal stomach and duodenum. Occult blood had left the stools in three days. The patient has been back at his busy practice for over two years since and has taken no precautions, he has smoked and has taken alcohol without any further trouble.

The last example was that of a doctor who on account of supra orbital neuritis kept himself going in his practice by taking aspirin. This had been proceeding for ten days when one morning he awoke with pain and took two aspirin tablets without water or milk as had been his custom hitherto. A quarter of an hour later he felt a slight epigastric pain, the same day four or five hours later he felt faint and had colic and soon passed stools containing a little visible blood and a large amount of tarry material. The value of this instance is that he had his alimentary tract examined by x rays and a fractional test meal and a blood count done four or five days before this occurred and apart from a hyperchlorhydria he was shown to be normal. The investigations were purely precautionary as he had reached middle life (41 years). After the melanin which lasted for three days his haemoglobin was 58 per cent. In spite of this he carried on at work and made a complete recovery. When radiographed twelve days after the bleeding again no abnormality was found. He had never had any symptoms of indigestion and has had none since although two years have elapsed.

The last two cases I believe illustrate the susceptibility of the gastric or duodenal mucosa especially in the presence of a high acid to what are regarded as minor sources of irritation—in the one alcohol or possibly salted almonds in the other free acid liberated from aspirin.

Clearly it is of practical value to realize that profuse haemorrhage may occur as the result of chronic gastritis on the one hand or comparatively slight trauma in the presence of hyperchlorhydria on the other hand otherwise these patients might well be condemned to irksome and superfluous restrictions. The more our knowledge of the stomach increases the greater does the value of special methods of investigation increase. It is only by these that we can be certain of such diagnoses as gastritis and mucosal atrophy. Many people presenting test meals of a type suggesting gastritis have no symptoms whatsoever. In the past it has been assumed that gastritis was present if there was hypochlorhydria or achlorhydria associated with an excess of mucus. On the other hand the finding of hyperchlorhydria which is seldom associated with an excess of demonstrable mucus was not thought necessarily indicative of gastritis. Too much importance has been attached to what has been regarded as an excess of mucus in the past. The less the acid secreted the more will the mucus appear to be although there may be no true absolute increase. Conversely in highly acid specimens mucus when present is masked and is very difficult to detect. The most obvious appearances of gastritis as seen through the gastroscope are usually to be found in a hyperchlorhydric stomach in which test meals reveal no mucus. In short a hypertrophic gastritis that is very liable to superficial erosions and bleeding will give a test meal of hyperchlorhydria more often than not. In cases of achlorhydria or hypochlorhydria there is apparently a great excess of mucus so much so that it is difficult to obtain specimens through the tube and it in addition blood or pus cells are detected microscopically in the test meal deposits and again if the test meal has an unpleasant smell it is probably correct to assume that chronic gastritis is indeed present.

The value of the gastroscope lies mainly in three directions. (1) Giving a clear view of the gastric mucosa from which one can say with some degree of certainty that gastritis is or is not present. (2) Indicating whether an ulcer which has apparently healed according to occult

blood tests and x ray examination has in fact healed or not. Usually it has not and it requires many more weeks of treatment after the signs are absent before sound healing has occurred. (3) To determine whether an ulcer is malignant. A malignant ulcer can occasionally be recognized as such when x rays have failed to observe it on its irregular edge.

**X Rays**—The combination of the use of small quantities of barium emulsion smeared over the stomach and duodenum and the development of apparatus which allows of aimed exposures if necessary with compression makes such an advance in radiographic technique that given enough experience in interpretation there is seldom any possibility of error in the diagnosis of peptic ulcer or genuine as opposed to imaginary disease of the appendix. The only common mistake is to diagnose gasitis too readily but this aspect will gradually be checked by the extended use of the gastroscope.

The most important contribution to gastroenterology which has been made in recent years is provided by Magnus and Unglev (1933). Immediately after death from peritonitis and in the stomachs were fixed the introduction of formalin through a stomach tube. The autopsy showed that the characteristic lesion was one of atrophy of all the stomach coats in the region of the fundus and the body mucosa. The pyloro-duodenal region which was hitherto supposed to be responsible for the production of the intrinsic factors necessary to the health of blood and spinal cord was quite normal. Furthermore there was nothing to suggest the proposition—that is gastritis—had preceded the atrophy. Gastroscopy confirms the localization of the trouble.

Fifteen years ago when the orthodox treatment for gastric and duodenal ulcer was prolonged rest in bed and two hourly feeds of milk and milk foods until the stools became free of occult blood I abandoned this procedure in favour of a liberal though soft diet allowing milk cereals bread and butter honey fish and egg and plenty of fruit and vegetable after one week of rest in bed on milk only. I have had no reason to regret it. I had not the strength of my convictions when dealing with cases of haematemesis until reading of the most impressive series produced by Meulengracht (1933) who gave test meals exhibiting haematemesis and melæna a liberal diet including even meat provided the food was soft and the solid food was served as purée with the most excellent results. He points out quite rightly that it is desirable that the stomach should not be empty of food and thus contain free gastric juice which may be highly acid and therefore detrimental to the ulcer which is bleeding. Furthermore the prolonged starvation of the patient and even deprivation of an adequate amount of fluid when was so common in the past could only give rise to anxiety restlessness and diminishing recuperative powers. His method of feeding has now become fairly general in our hospitals, and the claims have been fully vindicated.

#### Regional Ileitis

Localized inflammation of the small intestine has recently been holding the centre of medical attention. Crohn Ginzburg and Oppenheimer (1932) reported thirteen cases in which it was in the terminal foot of the ileum. It appeared to begin in the ileo-caecal valve and produced ulceration and destruction of the mucosa with thickening and inflammation of the outer coats and considerable narrowing of the lumen. Abscesses and fistulae were reported. Since that time it has become clear that the condition may occur not only in the ileo-caecal region

but also at other points in the course of the ileum. Microscopically the lesion is seen to consist of a benign granuloma often presenting giant cell systems, and thus giving rise to the mistaken assumption that the condition was one of tuberculosis. This has been disproved not only by microscopical examinations but also by guinea-pig tests. The symptomatology is a varied one, but with adequate care it is probable that many cases can be diagnosed before operation. The picture may be like that of ulcerative colitis, with diarrhoea, pain, and fever, or again perhaps more frequently, there is central abdominal pain and recurrent distension of the abdomen, gradually giving rise to a permanent picture of chronic intestinal obstruction. By this time a mass can often be palpated in the right iliac fossa or elsewhere in the abdomen. Loss of weight and anaemia are also fairly constant features. A sudden attack of pain, with tenderness and some rigidity in the right iliac fossa, has often led to the removal of a completely harmless appendix. This should be taken as a warning against the employment of minute incisions for the removing of an appendix, when a larger one would have brought into view the diseased area of the bowel. If found in the early stages the treatment is satisfactory, and consists of resection of the affected portion. X rays will help in the later stages by showing a filling defect and partial obstruction of the ileum.

#### Intrathoracic Disease

The biggest advance in the diagnosis of pulmonary disease is due to the more general appreciation of the value of the bronchoscope. The discovery of a small carcinoma of a bronchus is thus made possible, it may explain the presence of a lung abscess, the persistence of a cough or even the sudden development of auricular fibrillation or flutter in a hitherto healthy patient. Why this remarkable association exists is still a matter of doubt. Now that surgery no longer shudders at the removal of a lung such early diagnosis is of very real importance.

Tomography allows of the taking of x-ray pictures of the lungs in different planes, while the other planes are sufficiently suppressed as not to interfere with a clear visual examination of the area inspected. This is particularly helpful in relation to cavities, whether tuberculous or those arising from non-tuberculous abscesses.

O Shaughnessy's cardio omentopexy for angina pectoris and persistent disability from cardiac infarction is the outstanding achievement of present day surgery. The balanced judgment of physician and surgeon in choosing suitable cases of coronary disease is an essential to success.

#### Pharmacological Advances

Of *prontosil* and its derivatives so much has been written lately that it would be pointless for me to do more than pay homage to this remarkable drug, the uses of which I have summarized in a recent paper (1937a). The haemolytic streptococcus, the *Bacillus coli* the gonococcus and probably the meningococcus are all susceptible to its influence the first, however far and away the most constantly so. Likewise of *gold* in the treatment of rheumatoid arthritis I shall say little, except to emphasize the fact that it is of much greater value in treatment than any preparation used hitherto, but it also carries with it many dangers, to which I have already made reference (Douthwaite, 1937b).

*Eumydrine* (atropine methylnitrate), the dose of which is a sixteenth to a thirtieth of a grain, is a valuable anti-

spasmodic, and less poisonous than atropine sulphate. It appears to have revolutionized the treatment of congenital pyloric stenosis in infants and converted it into a medical rather than a surgical problem to the benefit of the infants.

A valuable addition to our pharmacological resources is *zinc-protamine-insulin*. The object of this preparation is to produce an insulin which is absorbed slowly and will therefore have its action spread out more evenly throughout the day, and thus approximate as closely as possible to the normal production of insulin by the pancreas. The action starts in about nine hours and reaches its maximum in fifteen to twenty hours after injection. A single administration of ordinary insulin and the zinc preparation in the morning may thus suffice for daily treatment.

The success of *measles convalescent serum* was so great that in an epidemic it was often impossible to obtain supplies. This difficulty has been overcome in the most surprising way by the finding of an effective anti-measles *placental extract*. A dose of 5 ccm at the first sign of pyrexia, headache, or Koplik's spots will either prevent the rash entirely or render the disease of trivial severity. Smaller doses given earlier in the incubation period will have a similar effect. When we think of the frequency and severity of complications and sequelae of measles it is clear that this discovery is of the greatest benefit to mankind.

*Endocrines*—The development of endocrinology has already led to therapeutic results that are little short of startling. One can safely predict the profound effect it will have on medicine of the future, for we are no longer employing foreign substances to influence body activities but rather the very essences of the mysterious life forces. Already we can alleviate the mental and physical disturbances of the menopause with oestrin, we read of virility given to eunuchs with testosterone, and before long I hope we shall have means to control the obesity of pituitary or hypothalamic dysfunction. Yet we must progress cautiously and sift the evidence of efficacy with care lest endocrinology fall into the disrepute so justly meted out to wholesale vaccine therapy and other vagues. Nowhere is this more important than in dealing with male impotence acquired after a period of normal function. So often the cause lies in the mind, and its cure is suggestion. Parkes (1938) clearly summarizes the work on the efficacy of hormones in relation to absorption rate, and reveals the remarkable fact that the more complete purification of the essential extract results in reduced effectiveness on administration. This is due to the hormone being too rapidly absorbed. To counteract this tendency such combinations as testosterone propionate or oestradiol benzoate have been devised.

# SEROLOGICAL EXAMINATION OF HAEMOLYTIC STREPTOCOCCI FROM ACUTE RHEUMATIC AND CONTROL GROUPS

BY

C. A. GREEN, M.B., D.P.H.

(From the Bacteriology Department University of Edinburgh)

The association between inflammation of the upper respiratory tract and the rheumatic state has long held clinical recognition. The evidence on which this has been based was supported by the frequency with which tonsillitis occurred in rheumatic patients; statistical data being supplied by the work of St Lawrence (1920) Ingberman and Wilson (1924) Poynton (1925) Bertram (1925) and McCulloch and Irvine Jones (1929). In these investigations the incidence of throat infections was found to vary from 22.4 per cent to 77 per cent. Additional proof of the prevalence of repeated infection was found in the condition of the fauces. Thus the St Thomas's Hospital data in the Medical Research Council (1927) Report on rheumatism showed that the proportion of healthy throats in children of non-rheumatic families was greater than that in rheumatic families. In a similar controlled investigation Lambert (1920) found that in 1000 consecutive cases of rheumatism the proportion of unhealthy tonsils was 25.3 per cent as compared with 17 per cent in 250 cases of acute pneumonia. Active infection as indicated by inflammation of the throat was present in 22.4 per cent and 0 per cent of rheumatic and control groups respectively. Perhaps a more striking demonstration of the connexion between the two conditions is supplied by the occurrence of outbreaks of rheumatism mainly of recurrent attacks but sometimes primary after epidemic tonsillitis. Many examples of this sequence are described in the literature by Raven (1923) Boas and Schwartz (1926) Huler and Graef (1927-8) Glover (1930) Schlesinger (1930) Glover and Griffith (1931) Collis (1931) Sheldon (1931) Bradley (1932) and Coburn and Pauli (1933).

While there is thus considerable evidence for the occurrence of tonsillitis in rheumatism the bacteriological examination of the throat flora in such cases has yielded divergent results. Although the streptococcal genus has attracted most attention many species within the genus have been incriminated by different observers. Thus the work of Poynton and Paine (1900) stressed the importance of the alpha haemolytic or *viridans* streptococci. On the other hand Small (1927) and Birkhaug (1927) separately claimed aetiological significance for gamma or indifferent streptococci. Within recent years however beta haemolytic strains have gained increasing recognition in the reports of Glover (1930) Coburn (1931) Glover and Griffith (1931) Collis (1931) and Bradley (1932). Similar investigations such as that described by Schlesinger (1930) have led to the view that no single type of organism could be recognized as responsible for all infections but that many species were involved. It may be noted that in the majority of investigations in which beta haemolytic streptococci have appeared important the type of nasopharyngeal infection has been of the epidemic variety in enclosed populations such as those of schools, hospitals and training quarters. Thus the importance of Mantle's observation in 1885 at the beginning of the bacteriological era that rheumatism was a more common complication of infectious sore throat than of sore throat of a non-infectious nature becomes manifest. Even in sporadic

cases of rheumatism such as in the series of Gibson Thomson and Stewart (1933) beta haemolytic streptococci were isolated from the throat secretions of 43 per cent of patients as compared with 20 per cent of controls. It is commonly recognized that haemolytic streptococci from human sources differ greatly in pathogenicity as determined by virulence tests in experimental animals but the method is not suitable for extensive investigations nor does the pathogenicity in man and animal always concur. Lancefield (1933) by means of a precipitation reaction claimed that haemolytic streptococci could be divided into groups each of which possessed a common group specific carbohydrate fraction (M). Furthermore Group A represented the important pathogens in the human subject. An important practical application of this test was the demonstration by Lancefield and Hare (1935) that the majority of strains causing puerperal infection of the uterus were Group A in character. But as the majority of strains in the birth canal during a normal puerperium were not A, Lancefield (1935) suggested the main source and habitat of Group A strains is probably the human nasopharynx but not all commensal strains in this site belong to Group A. Hare (1935) for instance examining the nose and throat of normal human beings noted that only about one-third of haemolytic streptococci isolated were Group A, the carrier rate of this type in a normal population being estimated to be approximately 7 per cent. The relatively low proportion of commensal Group A strains in normal persons has been confirmed by Davis and Guzzard (1936) who recorded a carrier rate of 3 per cent. Again Plumier (1935) classified all but two of 415 strains from human infections in Group A but found that many strains from healthy subjects were not of this group. However a much higher proportion of carriers has been recorded by Kodama (1937) who found that 68 per cent of fifty normal subjects were in this category.

Clearly this method of examination may yield information concerning the part played by haemolytic streptococcal infection of the nasopharynx in rheumatic subjects and the present paper records data obtained by its application.

## Methods

### ISOLATION OF STRAINS

On admission to hospital with rheumatic manifestations a throat swab from every patient was plated on 5 per cent horse blood agar. Incubation was maintained at 37°C for twenty-four hours under aerobic conditions. If colonies of haemolytic streptococci appeared save all were replated and from the second plate if a pure growth resulted stock cultures were prepared by inoculation of a tube of cooked meat medium. After twenty-four hours incubation at 37°C the stock culture was stored at 0°C. Throat swabs from control subjects were similarly treated.

### PRECIPITIN REACTIONS

Rabbit antisera against representative strains of Lancefield groups A to H were prepared by serial inoculation of formalized cultures over a period of six to ten weeks. The carbohydrate antigen required for the test was prepared by inoculating a 5 ccm horse digest medium from the stock culture of the strain under investigation. After twelve hours incubation at 37°C the 5 ccm broth culture was added to 50 ccm of the same medium. The heavy growth after eighteen hours incubation was deposited by centrifugation and washed four times in sterile normal saline. After the final washing 2 ccm of sterile saline containing hydrochloric acid to a concentra-

tion of N/20, was added to the deposited cells, and the mixture transferred to a water bath at 100° C for ten minutes. After rapid cooling and centrifugation the supernatant extract was removed and neutralized by the addition of sodium hydroxide. The clear supernatant fluid after further centrifugation was the antigen used in the test.

### Results

For this investigation two groups of subjects were selected, each numbering 200 and constituted as follows:

**Group R**—Patients admitted to hospital with one or more symptoms of acute rheumatism, including arthritis, carditis chorea, etc. This group included subjects with both initial and recurring attacks.

**Group NR**—Patients in the same hospital wards as members of Group R, but without existing or previous manifestations of rheumatism. This group included all types of diseases, and no discrimination was made as to the presence or absence of nasopharyngeal infection, as will be seen hereafter.

#### HISTORY OF THROAT INFECTIONS

At the time when a throat swab was taken every patient was questioned as to the occurrence of any symptoms of nasopharyngeal infection during the preceding six weeks. As indicated in Table I, in 156, or 78 per cent,

TABLE I—Results of Throat Swab Examination in Rheumatic Group (R) and in Control Group (NR)

	Rheumatic Group (R)	Non Rheumatic Group (NR)
History of recent nasopharyngeal infection	156 (78%)	93 (46%)
Haemolytic streptococci isolated	95	26
No history of recent nasopharyngeal infection	44 (22%)	107 (54%)
Haemolytic streptococci isolated	21	33
Total number from whom haemolytic streptococci were isolated	116 (58%)	59 (30%)

of the rheumatic group R a history of such an infection was obtained. On admission to hospital with rheumatic manifestations the throat symptoms had entirely subsided in the majority of cases, although enlarged tonsils were often found. Turning to the control group NR, a high figure of recent infection was also found—namely, in 93, or 46 per cent.

#### INCIDENCE OF HAEMOLYTIC STREPTOCOCCI IN THROAT SECRETIONS

From the throat swabs taken on admission from Group R haemolytic streptococci were isolated in 116, or 58 per cent of patients. In the case of the control group NR, fifty-nine or 30 per cent were found to be carriers. Considering the results in respect of recent throat infection, ninety-five or 60 per cent, of the 156 rheumatic patients with a positive history gave positive cultures of haemolytic streptococci whereas twenty-one, or 47 per cent of the remaining forty-four with a negative history yielded positive cultures. In the control group NR the haemolytic streptococcal carrier rates in these patients with and without known recent infection were 28 and 30 per cent respectively.

#### SEROLOGICAL TYPES OF STRAINS

Applying the precipitin test in the examination of all strains of haemolytic streptococci isolated from the two groups of patients the results detailed in Table II were

TABLE II—Serological Grouping of Haemolytic Streptococci Isolated from Throat Swabs of Both Groups

Lancetfield Group	Rheumatic Group (R)				Non Rheumatic Group (NR)			
	No. of Strains from Patients with Recent Nasopharyngeal Infection	No. of Strains from Patients with no Recent Nasopharyngeal Infection	Total	Percentage of Total No. of Strains (116)	No. of Strains from Patients with Recent Nasopharyngeal Infection	No. of Strains from Patients with no Recent Nasopharyngeal Infection	Total	Percentage of Total No. of Strains (59)
A	81	17	101	87	18	7	25	42
B	2	1	3	3	2	7	9	15
C	4	2	6	5	3	13	16	27
D	0	0	0	0	0	1	1	2
E	0	0	0	0	0	0	0	0
F	0	0	0	0	0	0	0	0
G	5	1	6	5	2	4	6	11
H	0	0	0	0	1	1	2	3
Total	95	21	116	100	26	33	59	100

obtained. The most important of the data secured was the high proportion of Group A strains isolated from Group R patients as compared with Group NR. Whereas the difference in incidence of haemolytic streptococci—namely, 58 per cent and 30 per cent respectively—in these two groups was notable, the difference in the incidence of Group A infection was even more significant, the respective incidences being 50.5 and 12.5 per cent. Further, it was found that although the majority of persons in the control group with a history of recent infection were Group A carriers, only seven of thirty-three persons without recent symptoms were carriers. On the other hand, rheumatic subjects irrespective of subjective symptoms of infection yielded Group A strains in the majority of instances where haemolytic streptococci were isolated.

#### Commentary

The number of subjects in each of the two groups examined was considered large enough to enable reasonable comparison to be made. A high incidence of sore throats in the rheumatic group—namely, 78 per cent—was not unique, but approximated to that found by St Lawrence (1920) and Ingerman and Wilson (1924). In the unselected control group it was surprising to find the incidence of recent sore throats to be as high as 46 per cent, but for purposes of comparison in regard to the bacteriological investigations this was a fortunate circumstance. As haemolytic streptococci were recovered from 58 per cent of all rheumatic subjects on admission to hospital in indication was obtained of the extent to which this type of organism was responsible for the preceding throat infection noted in many of the series examined. It is recognized that tonsillar infections with this organism, as in scarlet fever, are followed by the carrier condition for indefinite periods, and it was reasonable to assume the same sequence in the present investigation. Of rheumatic patients with subjective symptoms of preceding infection 60 per cent yielded haemolytic streptococci, whereas in the symptomless the carrier rate of 44 per cent was still high. On the other hand, in the control group, despite the prevalence of apparent recent infection, only 30 per cent yielded haemolytic streptococci, and approximately the same proportion of carriers was found in those with and without a recent history. This would suggest with

that in the control group many of the throat infections were due to organisms other than haemolytic streptococci or that the carrier condition after faucial infection was less persistent than in rheumatic subjects.

Regarding the Lancefield grouping of the isolated strains it was interesting to find that 57 per cent of those from rheumatic subjects were of the important pathogenic Group A whereas only 42 per cent of strains from controls were of this type. Nevertheless even in the control group the majority of carrier strains from persons with a definite history of recent infection were also members of Group A.

### Conclusions

1 Of a group of 200 subjects with acute rheumatic manifestations 75 per cent gave a history of antecedent throat infections, 46 per cent of a non-rheumatic control group gave a similar history.

2 Throat swab cultures for haemolytic streptococci were positive in 58 per cent and 30 per cent of the rheumatic and control groups respectively.

3 Of the strains of haemolytic streptococci from throat swabs of rheumatic subjects 57 per cent were serologically classified in Lancefield Group A, 42 per cent of strains from non-rheumatic controls were of this group. Group A strains were therefore isolated from 50.5 per cent and 12.5 per cent of the rheumatic and control groups.

4 The evidence supports the relationship between infection with haemolytic streptococci and the rheumatic state.

I am indebted to the physicians of the Royal Hospital for Sick Children, the Royal Infirmary and the Municipal City Hospitals of Edinburgh for granting access to cases under their charge. It is a real pleasure to acknowledge the co-operation of Dr John G. Sclater in the collection of specimens.

The investigation was completed under tenure of a grant from the Harmsworth Fund for Research on Endocarditis, London.

## ACUTE EPIDURAL ABSCESS

BY

W R D MITCHELL, M.B., F.R.C.S. Ed.

Late Resident Surgical Officer Beckett Hospital, Barnsley

Recorded cases of acute epidural abscess are still uncommon and even more rare are reports of recovery. Hence I feel justified in describing one further successful case.

Dandy in 1926 collected twenty-five cases from the literature of these four were diagnosed during life two ending in recovery, the mortality therefore being 90 per cent. Abrahamson, McConnell and Wilson in 1914 were able to collect records of sixty cases. Operation had been performed in thirty of these with survival in twenty—a total mortality of 66 per cent. In many of his operations on the recovery was incomplete. Craig and Doyle who in 1932 reported a case in which operation was successful came to the conclusion that up to that time Pott's abscess was the only authentic case of complete recovery. Incorrect as this statement appears to be in view of MacDonald's case report in 1928 it shows how extremely small must be the number of cases where full recovery has followed operation. It will thus be seen that the prognosis in the untreated case is uniformly fatal. There is no recorded instance of recovery without the aid of surgical intervention.

### Pathology

The epidural space exists only on the dorsal aspect of the dura and is present from the seventh cervical to the second lumbar vertebra. It contains a quantity of loose areolar tissue which in common with similar tissue elsewhere is slow and ineffective in combating infection. The dura anteriorly is in close apposition to the canal throughout its length. Infection therefore is usually found in the dorsal space except where osteomyelitis of a rib or vertebra or extension from an extrapleural abscess is the cause. Once the infection has entered the epidural space rapid spread would be expected and in most of the published cases the space was widely infected necessitating removal of many laminae. However sometimes a circumscribed form of abscess occurs and it is reasonable to suppose that most cases go through a stage where infection is localized and therefore more amenable to surgery.

Softening of the cord is a common finding in cases which come to necropsy and it has been suggested that this is due to toxins travelling in one way or the nerve roots or to ischaemia following on a thrombosis of the vessels as the changes are much more than can be explained by mere mechanical compression. The organism in the reported cases has been either *Staphylococcus albus* or *Staphylococcus aureus*.

### Aetiology

Cases fall into three groups: (1) those where extension from a neighbouring source of infection can be traced; (2) those arising by metastasis from a distant infection; (3) those in which no primary focus can be demonstrated. Trauma is mentioned by several writers as an inciting agent but it is difficult to prove that it is.

### Diagnosis

Diagnosis may present difficulties but writers are unanimous in stressing the appearance of early and persistent pain localized over the site of the abscess or radiating along the nerve roots. Temperature varies but

it is usually indicative of an infective process. Motor symptoms may take several days to appear and then develop slowly or, on the other hand, a complete paralysis of the lower limbs may occur in a few hours. In some cases the toxæmia seems to have so overwhelmed the patient that paraplegia has not had time to develop before death. The paralysis may be partial or complete, and of flaccid or spastic type. Probably most cases go through a stage of spasticity with increased tendon reflexes and extensor plantar responses. Sensation in the reported cases varies from widespread anaesthesia to little or no disturbance at all. It has, however, in several instances given the clue to the position of the abscess. Localized oedema over the tender area is mentioned by a few and is probably found more often than reports would indicate. Usually the sphincters are affected, and retention of urine may be a comparatively early sign.

Clinically, therefore, the diagnosis is based on (a) pain over and in the spine, with or without root radiation, (b) variable signs of toxæmia, (c) a variable degree of cord lesion. Of these, the first-named is the most constant, but the case may present itself with any one of the three signs as the outstanding feature. Radiographs are of no value unless there is an accompanying osteomyelitis of a rib or vertebra.

Lumbar puncture at the usual site should be performed, this may reveal pus from the abscess, xanthochromia and increased protein, or a normal fluid which may or may not be under tension. Puncture at the site of maximum tenderness, while it may yield valuable information, is not without danger. It should be borne in mind that if the subarachnoid space is not obliterated by the abscess pressure it will be very easy to introduce infection and start a purulent meningitis. Lipiodol is advocated as an aid to diagnosis but its value seems limited, and it may serve only to prolong the pre-operative period and so prejudice the patient's chance of recovery. The more severe pain and tenderness with the evidence of spinal block, differentiates acute epidural abscess from myelitis, thrombosis, and embolism. Examination of the cerebrospinal fluid, and the different type of pain, eliminate meningitis and poliomyelitis. Stiffness of the neck and a positive Kernig sign are found in many spinal conditions, and help very little with the diagnosis.

### Treatment

Treatment consists in early and adequate drainage by laminectomy. Where the infection is widespread the extensive removal of laminae, as done in some of the published cases, seems hardly justified in view of the extremely poor prognosis. In the case of local collections of pus the removal of one lamina is probably sufficient.

### Complications and Prognosis

All writers emphasize the extreme acuity of the condition and the rapid deterioration of the patient where surgery is either not employed or is delayed until the infection is generalized and septicaemia established. Without operation all the patients die of extreme toxæmia, septicaemia, or meningitis in one to three weeks.

Prognosis obviously depends on (1) the virulence of the infection, (2) the resistance of the patient, and (3) the stage at which operation is performed. Where the operation is done early and the infection is found to be localized full and complete recovery may be expected.

### Case Report

The patient, a girl aged 15, was admitted to hospital on September 15, 1937, complaining of pain in the back and

headache. She was at work on September 12, but had to leave on account of pain low in the back and a feeling of weakness in the legs. Appetite was poor, the bowels were constipated, and when admitted she was unable to void urine.

**Examination.**—On admission her temperature was 101° F and pulse 90. There was no demonstrable focus of infection and nothing abnormal was found in the heart and lungs. The pupils were equal and reacted to light and accommodation. The cranial nerves were normal, as were the upper arms. Abdominal reflexes were absent. The lower limbs showed marked rigidity. Kernig's sign was positive, knee and ankle jerks were very exaggerated on both sides, and there was a bilateral extensor plantar response. No hyperaesthesia or loss of sensation was observed. The abdomen was distended and the bladder well above the pubis. Tenderness was present over the second lumbar vertebra, with some redness and oedema of the overlying skin. The bladder was catheterized and 40 ounces of urine were drawn off. Lumbar puncture between the second and third lumbar vertebrae resulted in 3 c.cm. of pure pus.

A few hours later, as pain and paralytic symptoms seemed to be on the increase, a diagnosis of acute epidural abscess was made and operation decided upon. In order to eliminate a purulent meningitis, cisternal puncture was performed after the patient was anaesthetized, and as the fluid was quite clear, though under considerable tension, it was decided to proceed with the laminectomy.

**Operation.**—This was performed under open ether anaesthesia, and consisted in removal of the first, second, and third lumbar spinous processes and the second lamina only. Pus welled up immediately the extradural space was opened, and seemed to come from under the third lumbar lamina rather than from under the second. At this stage it was thought that the third lumbar lamina should be removed as well, but when the forceps broke under the considerable pressure needed it was decided to be content with the drainage already provided. The dura was thickened and was covered by granulation tissue, and all subarachnoid space seemed to have been obliterated by the abscess pressure. No pulsation of the dura was noticed. A thick rubber tube of one inch diameter was inserted, resting on the cut-off laminar processes, the muscles and skin being sutured loosely around it.

**Subsequent History.**—The patient was nursed on her face on a water bed and the bladder catheterized twice daily for five days. Cystitis was prevented by the use of cystopurine and full aseptic precautions in catheterization. On the day following the operation the patient was completely comfortable, and remarked that her previous pain had gone. Incontinence of urine took the place of retention on September 20, and this was accompanied by incontinence of faeces as well. The latter ceased on September 28, and normal bladder control was resumed on October 5. Spasticity of the legs with exaggerated jerks and extensor plantar responses continued till December 14, and on discharge from hospital the reflexes were normal and the patient walked with a normal gait. Massage and electrical stimulation of the muscles prevented gross loss of muscle tone, and enabled the patient to walk six weeks after operation. Discharge from the wound was considerable at first, but soon ceased, and the drain was removed on the sixth day. Temperature was never above 101° F, and fell to normal sixteen days after operation. The pulse varied from 90 to 100, but settled with the temperature.

The patient was discharged on January 6, 1938, with a small granulating wound and slight serous discharge. When last seen on January 20 there was still a small granulating area, but the patient felt well and had resumed her full activities.

### Pathological Examinations

**Urine.**—Acid, specific gravity 1010, no albumin, sugar or organisms.

**Pus from Abscess.**—Pus cells and numerous Gram positive cocci were present, but *B. tuberculosis* was not found. A pure growth of *Staph. aureus* was obtained after aerobic cultivation at 37° C.

**Cerebrospinal Fluid from Cisternal Puncture**—White cells 23 per cmm red cells nil Differential count small mononuclears 20 per cent large mononuclears 80 per cent polymorphs nil *B. tuberculosis* was not detected and no growth was obtained after aerobic cultivation at 37° C

The Wassermann reaction was negative and the blood sedimentation rate 22 mm per hour on October 26 1937 and 11 mm per hour on January 1 1938

### Summary

1 A short review of the literature and an account of the condition are given

2 A case is described in which early operation was followed by complete recovery

3 The importance of full investigation in cases presenting severe and persistent pain in the back with motor symptoms in the lower extremities is stressed in order to eliminate a diagnosis of myelitis or poliomyelitis which would prevent an operation that might be the means of saving the patient's life

## SULPHONAMIDE CHEMOTHERAPY IN GENITO-URINARY (NON-GONOCOCCAL) INFECTIONS

BY

A J. COKKINIS, M.B., B.S., F.R.C.S.

Assistant Surgeon Wembley Hospital Assistant Director  
 Special Clinic and formerly Assistant Director  
 Surgical Unit St Mary's Hospital

During the past year I have treated with the recently introduced compounds containing the sulphonamide (NH SO<sub>2</sub>) and aniline (C<sub>6</sub>H<sub>5</sub>NH) chemical chains upwards of 900 cases infected by various organisms. A preliminary report (Cokkinis 1937) described my experiences in the treatment of gonorrhoea below are recorded the results obtained with these preparations in non gonococcal genito-urinary conditions. Experiences in their use for acute abdominal lesions and other surgical infections have also been extensive but are not reported in this paper. They have however, been of considerable interest and although there have been enough failures and disappointments to show the limitations and difficulties of this form of treatment the successes have been sufficiently numerous and striking to convince me that the new chemotherapy has very definite surgical possibilities which are worthy of further exploration.

### The Drugs Employed

**Sulphanilamide** (syn prontosil album streptocide sulphonamide etc.)—In my hands this appears to have the widest range of use and to offer the greatest bacteriostatic activity. Unfortunately it is much the most toxic of all these compounds and although haemolytic anaemia and agranulocytosis have not been my experience the less serious toxic manifestations have proved extremely common often troublesome and occasionally alarming

In surgical cases and after major operations (particularly abdominal and genito urinary) the most troublesome toxic effects have been prostration (sometimes severe) gastric irritation and cyanosis. I am now developing the conviction that sulphanilamide should not be given to debilitated patients or to major operation cases if a less toxic chemotherapeutic substance can be used, even though it may be of slightly lower bacteriostatic potency.

**Prontosil Soluble**—This azo dye compound which I have given by deep subcutaneous injection has so far in itself especially useful in operation cases for it causes neither gastric irritation nor prostration. The only toxic effect I have seen with it is a slight cyanosis and this in a very small proportion of cases. To obtain bacteriostatic action comparable to that of sulphanilamide it has to be given in rather large doses—for example 20 to 30 ccm of the 5 per cent solution daily.

**Prontosil Rubrum**—Of this I have as yet had little experience.

**Proseptasine and Soluseptasine**—These are remarkable free from toxic effects but in my experience their bacteriostatic action has proved somewhat disappointing and I have used them in only a few of my surgical cases.

**Uleron**—This new disulphonamide product which I am now trying extensively has shown a bacteriostatic potency in infections by several bacteria which include gonococci streptococci and coliform bacilli. In 100 cases of gonorrhoea (not reported here) and in a smaller number of surgical cases it has been extremely well tolerated and has shown no immediate toxic effects. The absence following its use of such symptoms as prostration cyanosis gastro intestinal irritation and cardio vascular effects makes it particularly suitable for debilitated and seriously ill patients—for example after major operations. One disadvantage however should be mentioned. This is the possibility of the appearance of toxic peripheral neuritis of a curiously constant and symmetrical motor distribution (adductors and opponens pollicis interosseous muscles of the hand and flexors and extensors of the toes and toes). This has occurred in less than 4 per cent of my cases and only when the drug was continued over a period of weeks. There is good reason for supposing that its administration is limited to a few days and once effect will not make its appearance even when large enough doses are used to obtain a rapid bacteriostatic action. Though uleron for the reason given above should not be used for long periods I believe that employed judiciously it may prove to be the non-toxic substitute for sulphanilamide which I have been looking for although on the whole it appears to be less potent.

In debilitated cases and those suffering from a severe surgical illness or recovering from a major operation when rapid bacteriostatic effect is required over a short period the drug used should not add in the way of toxic manifestations to the strain already imposed on the patient. For this purpose I have employed prontosil soluble in the past but I am now combining it with uleron with promising results. When however a bacteriostatic action is required for longer periods—that is more than a week or ten days—I still believe that sulphanilamide however toxic it may be is the best and safest substance to employ in most infections by sulphonamide susceptible organisms.

A total of fifty seven genito-urinary cases have been treated. These can be divided into three main groups:  
 (a) non gonococcal genital infections (thirty cases)  
 (b) primary urinary infections (five cases) and  
 (c) secondary urinary infections (fifteen cases)

## (a) Non-gonococcal Genital Infections

In this group are twenty-six cases of urethritis (males) and four of acute epididymitis. All gave negative tests for gonococci and complement fixation. One was an unmixed infection of *Strep viridans*, while ten were proved cases of mixed infection with various bacteria. Organisms were found in the other cases, but their exact nature was not proved by culture.

The following five cases were treated with uleron

improvement at all. One of the relapsed cases gave on culture a growth of *Strep faecalis*. *Staph albus* and diphtheroids one week after 40 grammes of sulphanilamide in sixteen days, the other two failures had no cultures taken.

## DISCUSSION

This group thus shows four cases of epididymitis with one failure and twenty-six cases of urethritis with three failures. It is interesting to observe that all five cases treated with uleron were successes, although the average

Case	Condition	Duration Before Uleron	Organisms Found	Total Uleron	Period of Uleron	Result	Follow up
1	Left epididymitis. Anterior and posterior urethritis	Seven days. No previous treatment	Coliforms on culture	16 grammes	Four days	Discharge ceased in two days. Testis normal in nine days	Still well three weeks later
2	Anterior and posterior urethritis	Nine days. Resisted previous treatment	Various organisms in smear. No culture	36 grammes	Six days	Discharge ceased in four days. Urine clear in seven days	Still well five weeks later
3	Anterior urethritis	Fifteen days. Resisted previous treatment	Strepts and diphtheroids in smears. No culture	18 grammes	Six days	Discharge ceased in five days. Urine clear in five days	Still well two months later
4	Anterior urethritis	Twelve days. Resisted previous treatment	Strepts coliforms and diphtheroids in smears. No culture	18 grammes	Six days	Discharge ceased in four days. Urine clear in three days	Still well three weeks later
5	Anterior urethritis	Twenty three days. Resisted previous treatment	Coliforms and <i>Strep faecalis</i> on culture	28 grammes	Seven days	Discharge ceased in one day. Urine clear in five days	Still well six weeks later

The other twenty-five cases were treated with sulphanilamide, and can be divided into two subgroups

## SUBGROUP I

This subgroup comprises three cases of acute epididymitis

*Case 1*—Right epididymitis with anterior and posterior urethritis of five days duration. Streptococci and diphtheroids in smears. Thirty three grammes sulphanilamide were given in fifteen days. Discharge ceased in one day, urine was clear in three days, and the testis normal in nine days. Patient still well two months later.

*Case 2*—Left epididymitis, with anterior and posterior urethritis of eighteen days duration. Resisted ordinary treatment. Coliforms and *Strep faecalis* on culture. Forty grammes of sulphanilamide were given in ten days. Discharge ceased and the urine was clear in two days and the testis normal in ten days (apart from small residual hydrocele). Still well two weeks later.

*Case 3*—Left epididymitis of twelve days duration with no signs of urethritis. Coliforms streptococci, and staphylococci in prostatic head. Twenty six grammes of sulphanilamide were given in seven days. No appreciable improvement.

## SUBGROUP II

This comprises twenty-two cases of urethritis, fourteen anterior and eight anterior and posterior, which are summarized as follows

The duration of symptoms (mostly intermittent) varied from three days to four years (average eight and a half months), and nearly all had resisted ordinary treatment. One case was a pure *Strep viridans* infection. Five were proved mixed infections with two or more of the following organisms: streptococci, staphylococci, coliforms and diphtheroids, in the remainder some of these organisms were seen in smears, but no cultures were made. The patients were given an average total quantity of 37 grammes of sulphanilamide over an average period of thirteen days.

Seventeen of the twenty-two cases were quite clear in one to seven days from the beginning of chemotherapy (average of just under three days) and were still well at an average period of nine weeks later.

Three cases failed to clear up. Two of them showed temporary improvement but relapsed later, one showed no

period before clinical cure was slightly longer than with sulphanilamide (approximately five days instead of approximately three days). It is also of interest to note that in two of the sulphanilamide failures staphylococci were found with other organisms.

The following case is worthy of special mention in view of the infecting organism

A man aged 24 had an intermittent urethral discharge and pyuria for four years, following repeated instrumentation for a congenital defect of the urethra. Examination revealed a purulent anterior urethritis, and two separate cultures gave an abundant growth of *Strep viridans*. Thirty five grammes of sulphanilamide were given in ten days with complete success: the discharge ceased after one day, the urine was clear in two days, while cultures taken on the fourth and seventh days showed no growth of *Strep viridans*.

## (b) "Primary" Urinary Infections

This group comprises nine cases of acute or subacute pyelitis and three of acute cystitis in which no other lesion was found in the urogenital tract.

## SUBGROUP I

All the pyelitis cases had an acid urine at the start of treatment. Two were reported as *B. coli* infections, four as coliform infections, and one as a mixed infection of "coliform and other organisms", the remaining two cases had no bacteriological examination.

One case (subacute pyelitis) was treated with uleron (16 grammes in four days). She was symptom free, with clear urine, after two days, and was still clear ten days later.

The other eight cases were treated with sulphanilamide, receiving an average quantity of 32 grammes over an average period of nearly eleven days, combined with large doses of alkalis. Five of them cleared up completely in from two to six days (two having previously resisted mandelic acid therapy) without subsequent relapse. The sixth case relapsed four days after 15 grammes (given in five days). In the seventh case it sulphanilamide was stopped after two doses, owing to severe vomiting, without improvement of the pyelitis.

The eighth case is of considerable interest and merits a detailed description

Mrs K. was admitted to hospital on January 25 1938 with acute pyelitis in the sixth month of pregnancy. At day she was very ill with rigors pain and tenderness in the right loin a temperature of 102 a pulse of 128 and heavy acid pyuria. Films of the urinary deposit showed very numerous pus cells and bacilli while cultures produced a heavy growth of coliform bacilli. On January 28 the temperature rose to 103 and sulphanilamide therapy was instituted. Three grammes daily were given for a period of thirteen days combined with alkalis. Within twenty-four hours all symptoms and signs of the pyelitis had subsided and the temperature came down to subnormal and stayed down. The urine cleared rapidly and became alkaline. On January 31 cultures showed but a moderate growth of coliform bacilli while on February 2 only a very scanty growth was obtained. Chemotherapy was discontinued on February 9 and she remained quite well until February 13 when a sudden relapse occurred. On the 16th she had rigors a temperature of 104 and pyuria with a heavy growth of coliform bacilli on culture. Three grammes of sulphanilamide daily were not given for a period of eleven days. The subsidence of symptoms this time was less dramatic and the temperature did not reach the normal till the fourth day. The urine however became quite clear again and cultures taken on February 25 proved sterile. Once again she remained quite well for one week after the end of the sulphanilamide course and then on March 6 relapsed as suddenly as before with rigors a temperature of 103 and heavy pyuria. Cultures taken on March 7 once more showed a heavy growth of coliform bacilli. A third course of sulphanilamide was now commenced and is still in progress. For the third time the infection has yielded completely to the chemotherapy but the patient is now beginning to reveal toxic effects and is showing signs of secondary anaemia. A blood count on March 10 gave 70 per cent of haemoglobin 3 200 000 red cells and 7 800 leucocytes. A serial temperature chart is appended.

Temperature chart of Mrs K. (pyelitis of pregnancy)  
Sulphanilamide treatment of relapses

#### SUBGROUP II

The three cases of primary cystitis had an acid pyuria. They all presented well marked basal symptoms (trigonitis) and two of them gave a culture of coliform bacilli. They received an average quantity of 22 grammes of sulphanilamide over an average period of approximately ten days. Two were quite clear after two days and did not relapse while under observation. The third was very intolerant to the drug and developed a relapse after clinical cure on a four day course of 3 grammes daily. This cleared up with a second course of 7 grammes in three days.

#### DISCUSSION

There was thus only one complete failure in this group of twelve cases the chemotherapy being abandoned on account of toxic effects. The rapidity with which the others cleared up was most striking but relapse occurred in more than a quarter of them. It may be of interest to observe that the average concentration of detectable sulphanilamide in the urine of these patients (on 2 to 3 grammes daily) was about 1 in 300 (employing the

sodium nitrite beta naphthol colour test against a standard solution of 1 in 5000)

#### (c) "Secondary" Urinary Infections

I now come to a group of fifteen cases of great surgical interest. They are examples of the secondary cystitis which complicates such lesions as senile enlargement of the prostate and stricture of the urethra. It is obvious that a rapid clearing up of urinary infection in such patients would prove of real value in the surgical treatment of the primary lesion and would also benefit cases

which for various reasons are no suitable for radical operation. For the sake of uniformity cases of gonococcal cystitis are not included in this series.

#### SUBGROUP I

This comprises nine cases of senile enlargement of the prostate with urinary infection. In four of them the chemotherapy was given before and after suprapubic prostatectomy in two before or after preliminary cystostomy in the other three no operation was performed. Brief details of the cases follow.

Cases 1-2 and 3.—These had moderate pyuria more than ounces of residual urine. One was a *B. coli* infection

the others had no culture of the urine. One received an average quantity of 10 grammes of sulphanilamide over an average period of five days within which the pyuria cleared up completely. All three had good renal function and in one age suprapubic prostatectomy was done at an average period of seven days after starting the chemotherapy. On minor toxic effects were produced by the drug but in two of the patients there were rather troublesome

After operation all three patients had prostatic glands (100 ccm of 1 per cent) injected twice daily for the first ten days. All the cases healed rapidly without delay of the operative step but it must be stated that the case of long saline irrigation for the first eight to ten days.

Case 4.—Moderate pyuria and renal insufficiency (blood urea of 110 mg). Catheter drainage was established and 2 grammes of sulphanilamide were given daily for three days. After this the urine was quite clear but the drug was discontinued owing to severe intolerance. At the end of one week suprapubic cystostomy was performed and suprapubic drainage established. A few days later the pyuria recurred and a culture of the urine showed coliforms *B. proteus* and streptococci. This again cleared up with 2 grammes of sulphanilamide daily for three days the drug being better tolerated this time. Ten days after the cystostomy the blood urea dropped to 25 mg and prostatectomy was performed. The after treatment and results were the same as in the above three cases.

Case 5.—A man of 69 with rigors pyuria and marked renal insufficiency. Two grammes of sulphanilamide daily for four days were well tolerated and produced an almost complete cure. Suprapubic drainage was established three days later and no further chemotherapy was given. Following the operation progressive renal failure developed and he died eight days afterwards.

Case 6.—A man of 74 with heavy pyuria and residual urine of 10 ounces. Suprapubic drainage (under local anaesthesia) was established at once with small self-clearing catheter after which 2 grammes of sulphanilamide were given daily.

He developed cyanosis and severe prostration after two days and the sulphanilamide was discontinued. By this time the urine was quite clear and remained clear for seven days, at the end of which time the blood urea had dropped from over 100 to 46 mg. The pyuria then recurred and increased, one culture gave coliforms only but a second three days later showed coliforms and *Strep faecalis*. The infection became worse, and the blood urea rose once more to over 100 mg. He was now given 3 grammes of uleron daily for four days, without toxic effects and the urine became clear again, although a growth of coliform bacilli was still obtained on culture. The blood urea dropped once more to 52 mg, and the prostate was successfully enucleated a few days later.

**Case 7**—Good renal function and moderate pyuria, which cleared completely with 9 grammes of sulphanilamide in four days, but the patient refused operation. The urine was still clear two weeks later, but further infection is likely.

**Cases 8 and 9**—These proved complete failures. Both are elderly hospital outpatients, with chronic retention of urine and a thick alkaline pyuria, showing very heavy mixed infection. One completely resisted a two-weeks course of 30 grammes of sulphanilamide which was well tolerated, the other has been on 2 grammes of sulphanilamide daily for six days without improvement.

It will have been noticed that (with one exception) these cases were given very small quantities of sulphanilamide. The drug was on the whole badly tolerated by these elderly patients, and I was afraid of doing additional injury to kidneys already damaged by obstruction. Actually, in no case was there the least evidence of toxic action on the kidneys, and in the one fatal case the renal failure could not in fairness be attributed to the sulphanilamide. Two thirds of the patients were definitely benefited by the chemotherapy, which proved of real service in combating both pre-operative and post-operative urinary sepsis, although it is of interest to note that the incidence of relapse (over 25 per cent) is the same as in the cases of primary urinary infection already submitted. On account of the marked intolerance to sulphanilamide shown by most of these elderly and debilitated patients I intend in future to make further trial of the less toxic uleron in its stead.

#### SUBGROUP II

This consists of four cases of urethral stricture with secondary cystitis, and one case of epididymitis with pyelocystitis.

**Case 1**—This patient was admitted as a case of acute epididymitis and (non-gonococcal) urethritis. After admission he developed symptoms of acute pyelocystitis with marked pyuria, a temperature of 103°, and pain and tenderness over the left kidney. Cultures of the urine showed a heavy *B. coli* infection. He was given 9 grammes of sulphanilamide in three days and responded in a few hours. On the third day he was symptom free with clear urine which on culture showed a very scanty growth of *B. coli*.

**Case 2**—Moderate bulbar stricture, with heavy (mixed) urinary infection. Forty-two grammes of sulphanilamide were given in two weeks. The urine was clear in four days and remained clear. Afterwards the stricture was treated by intermittent dilatation without recurrence of the infection.

**Case 3**—Moderately severe stricture with heavy pyuria. Forty-two grammes of sulphanilamide were given in two weeks. There was partial improvement after one week, but still slight pyuria at the end of the second week.

**Cases 4 and 5**—Severe strictures with severe cystitis and heavy alkaline pyuria and repeated attacks of retention. Three grammes of sulphanilamide were given daily for twelve and fourteen days. Case 5 was also given 4 grammes of uleron daily for four days. Symptoms of cystitis improved but pyuria slightly diminished only during chemotherapy, and relapsed afterwards.

#### DISCUSSION

The four complete failures thus far described in this group of cases of "secondary" urinary infection show a strange similarity. Two are cases of senile prostate and two are severe strictures, but they all had chronic retention of urine and an alkaline cystitis with heavy mixed infection. Whether their non-response to chemotherapy is due to the presence of sulphonamide-resistant organisms in the alkaline urine—for example, staphylococci or *B. proteus*—or to a submucous fibrosis of the chronically inflamed and thickened bladder can only be a matter for speculation. The fifteenth and last case in this group is also a chemotherapy failure, but for a very different reason.

Mrs R., aged 55, was first seen with a short history of intermittent cystitis and heavy pyuria. *B. coli*, *Strep faecalis* and other organisms were isolated from the urine, and she was given 3 grammes of sulphanilamide daily for one week. The urine cleared rapidly, but while still under treatment the pyuria recurred more heavily than before. Further investigation which included cystoscopy and laparotomy, revealed a carcinoma of the pelvic colon, with a very small vesico-colic fistula.

#### Conclusions

It seems both justifiable and opportune, on the basis of the experience reported here (which represents incidentally a small fraction of the total experience), to make a few comments on the mode of action and cause of failure of chemotherapy applied to these and other cases. It is obvious that bacterial sensitivity to these substances is highly selective. Indeed, it appears to vary not only with each group of organisms but also with individual strains of the same organism. No organism is 100 per cent susceptible, and it may be that few are 100 per cent resistant. Other things being equal, the highest incidence of success is likely to be obtained in infections by organisms which are highly susceptible as a group and which have the lowest proportion of resistant strains. A less obvious fact which experience suggests is that the susceptibility of a given strain may vary in the same patient from time to time, a highly susceptible strain becoming resistant after a while, or vice versa. This difference in degree of sensitiveness to sulphonamide compounds on the part of individual bacteria is well shown by the variation in what one might call the "effective" dosage. Thus where Meave Kenny (1937) found 1.5 grammes of sulphanilamide given daily sufficient to overcome coliform infection of the urine, Colebrook and Purdie (1937) have used from four to ten times as much as this for streptococcal infections of the puerperium.

The bacteriostatic action of the various sulphonamide compounds used in practice is also relative. In addition to differences in their general potency against the whole group of susceptible organisms, each may show some variation in its action against individual bacteria and even individual strains. Thus although sulphanilamide seems to inhibit a somewhat larger proportion of gonococcal strains than does uleron, the latter may succeed against an individual strain which has repeatedly proved resistant to the former. Furthermore, a strain of susceptible organisms may become "fast" to one compound and yet capitulate to another.

In my experience the coliform group possesses the lowest proportion of sulphonamide resistant strains and the highest degree of sensitivity to these compounds. This is particularly the case in infections of the urinary and genital tracts, where the growth of coliform bacilli can be rapidly arrested with quite small doses and where there is only a low proportion of failures. Gonococci are less

susceptible is a group requiring fairly intensive and prolonged treatment before they are completely and permanently eradicated, and there is a higher proportion of resistant cases. The high susceptibility of the haemolytic streptococcus (especially the A group) to sulphonamide compounds is well known but I have convincing evidence that certain non haemolytic streptococci—for example *Strep. viridans* and *Strep. faecalis*—can also be partly or completely inhibited by both sulphanilamide and uleron. I have also seen cases of mixed genito urinary infection in which such organisms as *B. proteus*, *B. aerogenes* and diphtheroid bacilli are concerned completely clear up with both those substances. The staphylococcus and the pneumococcus, on the other hand have proved almost entirely resistant in my experience.

It is now generally realized that whatever the exact mode of action of sulphonamide compounds may be they act only as blood borne antisepsics and their direct application to an infected focus is of comparatively little value. Reaching the blood and tissues quickly they are also rapidly excreted and in practice unless they are correctly administered their concentration will soon be found to fall to a subefficient level. An adequate blood supply to a focus of infection is of course an essential condition for success. Avascular foci such as blood clots, cardiac vegetations, necrotic areas and chronic foci embedded in scar tissue or sclerosed bone will resist chemotherapeutic attack no matter how susceptible the enclosed organisms may be.

One cannot help feeling that all these substances exert a purely bacteriostatic action and that they do nothing to stimulate the defence mechanisms of the host. The final result of any infection must largely depend on this defence mechanism and many failures with chemotherapy are probably to be attributed to its faulty operation. Again chemotherapy does not appear to have any action in neutralizing existing toxins or those liberated by the bacteria which these drugs destroy. Above all it in no way protects the patient against relapse or recurrence as is shown by the high relapse rate in the present series and in my other groups of cases. Indeed I have reason to believe that the opposite effect is sometimes produced and that chemotherapy at the very onset of an infection may actually inhibit those anti bacterial processes which confer immunity against recurrence or relapse of an infection. This would explain the fact observed in practice that a higher incidence of ultimate success is obtained when infections are treated some time after rather than at their onset.

Reflection on these and many other problems connected with the great therapeutic possibilities which have been opened by the discovery of sulphonamide compounds shows that a great deal of bacteriological and immunological work will have to be done before the new chemotherapy finds its proper level in the treatment of disease.

#### Summary

1 Clinical experiences are reported with several sulphonamide-containing chemotherapeutic substances (one of which recently introduced under the trade name of uleron is a di sulphonamide).

2 Fifty seven cases with illustrative records of genito urinary infection are reviewed.

3 In a group including four cases of epididymitis and twenty six of urethritis chemotherapeutically treated (in both instances non gonococcal) there were respectively one and three failures.

4 Twelve cases similarly treated and constituting a mixture of acute and subacute pyelitis and cystitis showed one failure and three relapses.

5 Fifteen cases of "secondary" urinary infection nine of them with senile prostatic enlargement four with urethral stricture one with epididymitis and one with vesico colic fistula were treated with these drugs. In the prostatic cases two thirds of the patients were benefited by chemotherapy which proved of value in combating pre-operative and post operative urinary sepsis although the relapse rate was again high. Two prostatic and two stricture cases—all with chronic retention and heavy alkaline mixed infection—completely failed to respond.

6 The selective action of these drugs on various organisms and strains and their mode of action *in vivo* are discussed.

## A NEW CONTRAST STAIN FOR GONOCOCCI AND MENINGOCOCCI IN SMEARS

BY

B. R. SANDIFORD, M.D.

*Chief Bacteriologist Public Health Laboratories, Cairo*

The examination of smears for gonococci particularly from women is facilitated by a method of staining described elsewhere (Sandiford 1937). It consists of Gram's method with Pappenheim's stain in place of a simple red counterstain. The organisms stain as in the usual Gram stain while the polymorph cells show blue violet nuclei and rose violet cytoplasm; the red gonococci standing out much more clearly against the blue violet background of cells than against the red background afforded by the ordinary counterstain. While the method was independently evolved an acknowledgment was given in the paper to Fauth (1918) who it was found had previously described a similar method of staining. Recently I have received reprints of papers by Scudder and Lisa (1931) and Scudder (1931) who apparently unaware of Fauth's paper described such a stain and recommended it for Neisseriae in sections and smears.

The present paper is the outcome of an attempt to devise a method of staining which would not diminish the contrast between cells and Gram positive organisms as does the Gram Pappenheim combination yet which would retain and if possible still further improve the contrast between Gram negative organisms and cells. To this end attention was directed to the staining of the Gram positive organisms and to the staining of the cells.

#### The Gram positive Organisms

**Effect of Acid**—It was found that when as soon as possible happened in dealing with large batches of routine specimens the counterstain was left on rather too long, the Gram positive organisms tended to decolorize. In view of the reported effect of acid vaginal secretion on the Gram staining of organisms (see below) it seemed probable that the 2 per cent carbolie acid which forms the bulk of Pappenheim's stain was responsible for this decolorization. Experiments on stained films with 2 per cent carbolie acid alone showed this supposition to be correct.

**The Violet Stain**—In preparation was edited by the use of crystal violet with ammonium oxalate as the initial stain and acetone as the decolorizer. (I am indebted to Major Beamish, R.A.M.C. for drawing my attention to the method which seems to be the same as that described

by Hucker, 1922) This stain gives a deep purple-black to Gram-positive organisms, and is more "fool-proof" in use than other violet stains Various authors mention the effect of acid vaginal secretion in producing spurious Gram negative results, and recommend the use of either alkaline violet (Burke, 1921) or alkaline iodine (Scudder and Lisa, 1931) Scudder (1931) advocates the use of a buffer with the initial violet stain, and says that the ammonium oxalate mixture acts as a buffered solution Its advantages for vaginal smears seem to be obvious

*The Decolorizer*—Whatever method of Gram is used, acetone is much superior to alcohol for decolorizing films containing pus With acetone, complete decolorization of the cell nuclei may rapidly be obtained and the Gram-positive organisms be left unaffected—a result which is difficult, or impossible of attainment with alcohol unless the smears are very thin and well spread

### The Cells

It seemed that if the violet element could be eliminated from the counterstain and the cells be stained green the contrast between them and both Gram-positive and Gram-negative organisms would be improved According to Lee (1937) this metachromatic effect of methyl green is due to the presence of methyl violet as an impurity With a view to obtaining a pure sample, Messrs Grubler were communicated with, but the one they sent gave no better results than their product which we were using A sample from British Drug Houses gave, just perceptibly, a purer green Scudder (1931) says that an over ethylated methyl green prepared by the National Aniline and Chemical Co was found to be practically free from violet impurity The results she got with it—dark blue-purple nuclei and faint lavender cytoplasm—however, suggest that they were much the same as those given by Grubler's product This is borne out by her statement that Grubler's iodine green produced similar results for I have found it to give the same colour as their methyl green

Various other dyes, as substitutes for methyl green, were tried in admixture with pyronine and other substances but without success Malachite green had seemed a hopeful substitute as both it and methyl green are basic colours This had been discarded however, as the sample we had available—pre-war, made by Lautenschlager—was practically insoluble However in view of our failure to find any other satisfactory substitute, and in view of the fact that according to McIntosh and Fildes (1931) malachite green is highly soluble in alcohol or water a sample was obtained from Messrs Grubler This proved to be freely soluble, and an aqueous mixture of it with pyronine in the proportions given below produced excellent results Used as the counterstain with the Hucker-Gram stain it gives a beautiful contrast between the bluish green cells the purple black Gram-positive organisms and the red gonococci Overstaining with it does not affect the Gram positiveness of organisms

In view of this success with malachite green it was surprising to find in Scudder's paper (1931) that Pappenhaim (1899) was quoted to the effect that one can use methyl green or iodine green but not malachite green in his stain

*Other Uses of the Stain*—I have found it useful also for detection of meningococci in cerebrospinal fluid and Gram negative organisms in centrifuged urine deposits, tissues and sputum It does not seem however, to be applicable to any sort of pus containing any sort of organism I have had the opportunity of trying it on only a few specimens of surgical pus and on only one

containing Gram-negative bacilli, which did not take on the pyronine well This substance is said to have a special affinity for Neisseriae (Scudder, 1931, Walton, 1936) My experience with vaginal smears has been that all Gram-negative organisms stain quite well with it Experiments with the counterstain below and films of *Bact coli* and *Bact typhosum* suggest that their affinity for pyronine is a function of their age In young cultures most of the organisms stain well with it, while in old cultures most of the bacilli take on the malachite green This factor of ageing and degeneration probably affects the affinity of Neisseriae for pyronine, as we have had irregular results with stale specimens of cerebrospinal fluid It should be noted that all the gonorrhoea specimens used in this work have been smears made by the clinician at the time of taking the specimen

The following is, the method of staining, now employed in these laboratories and in the British Military Laboratory in Cairo

### Method of Staining

Any Gram technique to which the worker is partial may be followed up to the end-point of decolorization, but the following is strongly recommended, especially the use of acetone, which is essential in order to obtain complete decolorization of the cell nuclei before counter staining

#### INITIAL STAIN

Crystal violet	1 gramme
Alcohol (98%)	20 c.c.m
Ammonium oxalate (1% aqueous)	30 c.c.m

- (i) Leave this mixture on the heat fixed film for half a minute
- (ii) Flood off with triple strength Lugol's iodine (is used in Jensen's modified Gram stain) and leave on for half a minute
- (iii) Pour off the excess iodine and blot once
- (iv) Decolorize with acetone for three or four seconds
- (v) Wash
- (vi) Put on the counterstain for two minutes
- (vii) Flood off with water—do not wash—and blot

#### CONTRAST COUNTERSTAIN

Malachite green	0.05 gramme
Pyronine	0.15 "
Aq. dest.	ad 100 c.c.m

N.B.—There are two varieties of pyronine B<sup>1</sup> and G<sup>1</sup>, the former being almost insoluble in water Pyronine (Grubler) is apparently pyronine G<sup>1</sup>, as it is freely soluble in water

*Keeping Qualities*—The following statements are based on haphazard observations only, during the use of solutions kept in ordinary bottles at room temperatures under 20° C

Crystal violet stain keeps for about a month, is found to have deteriorated after six weeks Counterstain keeps for at least three weeks, possibly longer 100 c.c.m. in a staining pot may be used for at least 150 small smears

### Summary

A method of contrast staining which greatly facilitates the detection of gonococci and meningococci in smears is described

By this method the cells and nuclei are stained bluish green, Gram-positive organisms purple black, and Neisseriae red

# Clinical Memoranda

## Popliteal Embolectomy

Mr J R Blackburn's case of femoral embolectomy reported in the *Journal* of April 2 (p 750) has suggested to me that the following case of popliteal embolectomy may be of interest

### CASE RECORD

A man aged 51 was admitted to Eveham Hospital on January 14 1937 suffering from auricular fibrillation. After digitalis therapy his pulse rate dropped to 75 per minute. In the early morning of January 25 he awoke complaining of severe cramp-like pain in both his legs. After a few minutes the pains died down to be followed by pain in the left leg below the knee. He was seen by me about two hours after the beginning of the pain when his pulse was thready and the rate 120 per minute.

**Examination**—The left leg was pale and cold and was paralysed from the knee down. Pulsation was felt in the left femoral but not in the left popliteal artery. The pulsation in the femoral artery was poor partly owing to his shocked condition and it was less strong than that of its fellow of the opposite limb. There was a localized area over the popliteal artery which was tender on pressure. The embolus had evidently first been held up at the aortic bifurcation and then been swept downwards to the left lower limb. A popliteal embolism was diagnosed and arrangements were made for operation the patient meanwhile being treated for shock.

**Operation**—About six hours after the initial symptoms the left popliteal artery was exposed by a posterior mid line incision under local anaesthesia. This incision was prolonged to expose the whole course of the vessel which in this case ended proximal and not distal to the tendinous arch between the origins of the soleus muscle. The popliteal vein appeared dilated and the circulation in it seemed to be at a standstill. The vein being retracted no pulsation was present in the last one and a half inches of the artery or in its terminal branches but distinct though sluggish pulsation was evident above that level in the artery itself and in the superior and inferior genicular arteries. Two light rubber covered mosquito forceps were applied one to the popliteal artery above and one to the anterior and posterior tibial arteries just below the bifurcation. A longitudinal incision one inch in length was made in the artery just above its terminal bifurcation the embolus delivered itself through the opening and was removed. On relaxing the proximal clamp there was strong and immediate pulsation of bright arterial blood. The proximal clamp was now closed and the distal one relaxed and then removed when some dark blood flowed slowly from the opening in the artery. The vessel was gently milked from below up but no fragments were obtained. The arterial wound was sutured with catgut and a small oozing spot was covered with the muscle graft fixed by a light mattress suture through the adventitia. On removal of the clamps strong pulsation occurred it being particularly noted that pulsation above the level of the embolus in the main and branch arteries was twice its previous volume. By the time the wound was closed the leg was pink and distinctly warmer. The limb was enclosed in cotton wool.

On the third day an ellipse of skin about three inches by two inches over the lateral surface of the lower third of the leg became discoloured but this passed off in three or four days. Otherwise convalescence was uneventful. Tests with a sphygmomanometer and a stethoscope three weeks and nine months after operation showed good circulation in the artery.

### Summary

Two interesting points are noteworthy

1 The point of tenderness which proved to be exactly over the site of the embolus

2 The poor pulsation of the main and branch arteries above the level of blockage and their striking improvement after removal of the embolus

This suggests a spasm proximal to the block which must militate to a large extent against the formation of an efficient collateral circulation

Eveham

G HARVEY DUNCAN, F.R.C.S.E.D.

## An Unusual Case of Miscarriage

The following case of miscarriage seems so unusual as to warrant publication

### CASE RECORD

A Chinese woman aged 36 was admitted to hospital on February 15 1938 with a history of having passed part of a foetus on the previous day. The patient said that she felt both arms part of the trunk and her head were missing but that she had hooked out the head later and had also passed a few small bones mixed with a foul smelling bloody stained discharge. Ten months previously she had had a miscarriage after five months' amenorrhoea and said that she had passed a placenta and an oval white mass about four inches long but she was very uncertain as to its appearance as she had fainted from severe haemorrhage. From her description the haemorrhage was probably treated by packing and injection without exploration of the uterus. After several days the haemorrhage ceased but the abdomen was still larger than normal. She returned to the country and for the next three months had short one-day menstrual periods after which she had almost continuous daily loss of blood stained discharge sometimes foul smelling for the next six months accompanied at times by bearing-down pains. She did not seek treatment as she said her appetite was good and she was able to do her work. It was not until she passed part of a foetus that she took her condition seriously.

After admission to hospital one or two foetal bones were expressed from the uterus on bimanual examination together with a copious pus-like foul discharge tinged with blood. For the first week after admission the patient had a temperature ranging between 101 and 99. The discharge continued with the passage of one or two more portions of the foetus at times. On the ninth day after two days of no menses a few fragments within reach of small ovum forceps were removed and the uterus washed out with glycine without an anaesthetic. There was no rise of temperature following this manipulation and as a slight discharge still persisted during the next five days it was decided to explore the uterus under anaesthesia. On March 1 after a vaginal dilatation of the cervix further small sharp fragments of small bones were removed with ovum forceps. The uterus was then explored again with a sound and a bone was touched at the fundus of the uterus apparently well embedded. This was gradually dislodged by douching with a flushing curette and hooking it with the sound till it was possible to grip it with ovum forceps and remove it though some damage was done to the cervical canal in the process as it lodged transversely across the internal os.

Following the operation there was fresh haemorrhage on the first day probably due to injury caused by the sharp edges of the bone but the temperature remained normal and the case was no further loss. The patient was discharged from hospital on March 7 in very good condition.

Possibly this was a five months' miscarriage of twins one foetus and the whole placenta being passed on the first occasion and the disintegrated remains of the second foetus ten months later or the portions passed on the two occasions may all have been parts of the one foetus.

## Reviews

### ESSENTIALS OF MIDWIFERY

*A Short Textbook of Midwifery* By G F Gibberd, M B, MS FRCS MCOG (Pp 529 187 figures 15s)  
London J and A Churchill 1938

Two qualities are required of the writer of a "short textbook"—namely, the power of concise exposition and discernment in selecting the essentials of his subject. There are not many short textbooks of obstetrics, and Mr G F Gibberd's recently published work will be likely to receive an immediate welcome for the reason primarily, that he possesses the first named quality to a quite uncommon degree. He possesses also a wide and accurate knowledge of his subject and, in particular, of recent developments in its clinical aspects. He has had the great hospital, of which he is a distinguished alumnus, its particularly well-organized maternity district, and its pathological museum, as his main sources of inquiry and experience, it is also evident that he has drawn freely from his association with Colebrooke and Fry in the research department of Queen Charlotte's Hospital. Starting with these advantages the author could hardly fail to write a useful book, and it may be said without hesitation that the merits of his work are outstanding and should secure for it a notable success.

When space is limited the selection of subjects for the fullest possible exposition must be to some extent a matter of opinion and on the whole the author has shown wisdom in his choice, but there are exceptions. As an instance, we may quote his treatment of ante-natal care, a subject which in the judgment of obstetric teachers generally is of primary importance. Mr Gibberd, however, disposes of it in less than two pages, and he is content to present the 'objects of ante-natal care' in four bald statements which are so obvious in character as to resemble platitudes, and which could have been formulated by any intelligent senior student for himself. The indiscriminate practice of 'routine tests' is discouraged lest they should become an 'automatic ritual,' but the point must not be overlooked that the result of such tests is often the first indication of their being called for. The importance of establishing sympathetic and sustained contact between the patient and her doctor and nurse, particularly in the case of a primigravida, is overlooked, as is also the great assistance which can now be obtained in industrial practice from the public maternity services. Students and junior practitioners are usually in need of both exhortation and guidance in these matters. *En passant* the author surely loses, for the moment, his sense of proportion when he advises expectant mothers to spend ten hours a day in bed.

All authors are, perhaps, prone to discourse freely upon the matters in which they are particularly interested, it is therefore not surprising that the subjects of renal disease in pregnancy and of puerperal infection should receive comprehensive treatment. These sections are written with admirable clarity, the student who masters them will have nothing to fear from examiners, and will in addition be possessed of a store of knowledge which he can put to practical use. On the other hand the hormonal influences which control the reproductive cycle receive but perfunctory treatment, and the reader is given no inkling of the fascinating story of their elucidation—admittedly incomplete, is yet but stimulating to the mind of the thoughtful reader.

There is much in this book to commend and little to decry, if a short textbook of midwifery is needed no better could have been provided. The illustrations, and in particular the skiagrams, are admirable, and have almost all been prepared under the personal supervision of the author.

### PARENTS AND CHILDREN

*The Generations: A Study of the Cycle of Parents and Children* By Dr Emanuel Miller (Pp 276 7s 6d net)  
London Faber and Faber 1938

In this volume, which is an expansion of lectures given at the Institute of Medical Psychology, Dr Miller discusses the relationship of parents and children and seeks to show the causes of the frequent difficulties that arise in families and the way in which they might be avoided. His approach is founded on psycho-analysis, though he does not adhere to the strict Freudian doctrine, and he points out how difficult it is to break the vicious cycle, since many of the faults of parents are inexorably determined by their childish reactions to similar faults in their own parents.

The subject is a wide one. The history of the family in primitive peoples down to modern civilization is briefly reviewed in the first chapter, and an attempt to foresee what may happen to the family under modern social and political developments is made in the last. The intermediate chapters are occupied by a sketch of the problems which face those about to marry, the neurotic reactions to the responsibilities of marriage and parenthood, and the development of the child's character and personality in the family. Although it might be held that the subject matter of this book is not strictly medical, it is a problem of which few medical men can afford to be ignorant, and least of all the general practitioner under whose benevolent eye the family is founded and grows.

Dr Miller's book ought to interest everyone, medical and lay, and his deep erudition and wide range of interest will stimulate the reader to meditate upon a greater variety of questions than might be expected from the modest compass of a volume of little more than 270 pages.

### RENAL PHYSIOLOGY

*The Physiology of the Kidney* By Homer W Smith (Pp 310, 32 figures Frontispiece 15s net) London Humphrey Milford, Oxford University Press 1937

Professor Homer W Smith's book, *The Physiology of the Kidney*, is probably the most important work on this subject since Cushny's *Secretion of Urine*. Like Cushny the author takes us step by step over evidence compiled from the results of hundreds of experiments, summarizing and drawing conclusions as he goes, so that at the end the reader has a fairly clear picture of the present state of knowledge. In this survey the work of the author's own school takes an important place but is not given undue prominence. We see how the very simplicity of the Cushny theory is its greatest pitfall, and how the evidence for excretory activity on the part of the renal tubules, as well as reabsorption from the glomerular filtrate, is now incontrovertible.

The most important steps in this new knowledge have been the direct examination of glomerular filtrate by Richards and his co-workers, and the finding of a substance which is neither excreted nor reabsorbed by the tubules, and can therefore serve as a measure of glomerular filtration. The author shows how the polysaccharide inulin fulfils the necessary criteria for such a

substance. Using the inulin clearance as a standard the simultaneous clearances of other substances can be measured and their mode of excretion studied. The phenol red clearance for example is much greater than that of inulin showing that the former substance must be actively excreted.

In the study of renal physiology difficulties have constantly arisen owing to differences in the mode of excretion of certain substances in various species. Thus the creatinin clearance in the dog is the same as that of inulin but this is not the case in man. Even Cushny's idea of threshold substances is losing its meaning and on this subject the author says: "The problem is undoubtedly a very complex one in our ignorance the term threshold as descriptive of the more or less critical relationships between plasma level and excretion is too convenient to be abandoned. This sentence gives some idea of the critical spirit and at the same time the tolerant attitude in which the book is written. It is not too much to say that it will be read by every serious student of physiology. Apart from the clear exposition of a very difficult subject the reader will learn much about the fallacies which have been found and the pitfalls which await the unwary experimenter and a careful study of this book should avoid many mistaken conclusions in the future."

### PYORRHOEA ALVEOLARIS

*A Textbook of Clinical Periodontia: A Study of the Causes and Pathology of Periodontal Disease and a Consideration of its Treatment.* By Paul R. Stillman D.D.S. and John Oppie McCall D.D.S. Second edition completely revised and reset (Pp. 282, 44 figures, 15s. net.) London and New York: The Macmillan Company, 1937.

In the preface to this the second edition of their book on what is generally termed pyorrhoea the authors emphasize three points: that the dentist should focus his attention on health and the means for attaining it rather than on disease; traumatic occlusion; reattachment of gum to tooth where it has been destroyed by the ravages of pyorrhoea. Health seems to refer mainly to the alveolar structures. If either from overuse or disuse their tone fails the undifferentiated embryonic mesenchyme cells of the pericementum fail in their function of renovation thus showing the importance of normal function. This requires normal occlusion and any deviation from the normal which puts an unwonted strain on a tooth must be followed by disease of its supporting tissue. Such abnormal occlusion is called traumatic occlusion and is held by the authors to be the root cause of pyorrhoea. Fundamentally etiology may be stated as being based upon a disturbance of function: the only function of the teeth is mastication so it follows that overuse (traumatic occlusion) or disuse must be at the base of all dental disease. To the authors of this book malocclusion is the governing factor in the aetiology of pyorrhoea and the great point in treatment is to grind the bite till normal occlusion is attained. In the treatment of pyorrhoea pockets they claim that by presenting a scraped surface of cementum to a gum flap freed of epithelium reattachment of gum to root can be obtained. In Fig. 37—reattachment of gum to root—we note the absence of Sharpey's fibres: the reattachment may be only the cicatricial contraction of the gum on to a sterile root surface. Frankly we are unable to follow the authors' chain of argument—the work could with advantage be compressed to half its size—and we cannot see that they make a strong case for their thesis. The work, however, is worthy of careful study.

### HEALING PROPERTIES OF PLANTS

*Lehrbuch der Biologische Heilmittel.* By Dr. Med. Gerhard Madaus. Vols. I, II, III and index. (Pp. 286+76 plates, 1114 illustrations, RM 92 bound RM 235.) Leipzig: Georg Thieme, 1937.

The textbook of biological remedies by Dr. Gerhard Madaus is a massive encyclopaedia with abundant illustrations. Most of the plants used in medicine in the past or present are described in a series of monographs which occupy the bulk of this work. Each monograph contains an account of the geographical distribution and botanical characters of the plant and a history of its use in medicine. An account is also given of the pharmacological actions and the chemical nature of the active principles. Finally the monographs describe the therapeutic uses of the plants not only in official medicine but also in homoeopathy and in folk medicine. The monographs range from two to thirty pages in length.

The monograph on digitalis is one of the longest (thirty pages) contains a coloured plate and a page on the history of the medicinal use of the plant, five pages on the chemistry of the glucosides, a page of structural formulae and some twenty pages on its pharmacological actions and clinical uses. References are given to some of the most recent work on the latter subjects. The volumes therefore resemble in their general scope the old herbals with the addition of modern chemistry and pharmacology. The author explains in a preface that his general aim has been to collect all the information available about the healing properties of plants. He emphasizes the point that the experience of former generations is of value as well as the scientific knowledge that has been accumulated during the last century. Inspection of the volume shows that its contents have been largely chosen on the basis of folk lore. Adequate descriptions are given of most of the important galenic plants but the majority of plants described are not used in official medicine.

The appearance of this imposing encyclopaedia is perhaps a sign of the increasing interest that is being taken by the German authorities in German folk lore since the new *Weltanschauung* with its emphasis on racial traditions and the importance of subjective emotions in comparison to objective knowledge finds itself more and more in sympathy with the herbal medicine of past ages.

### IMMUNITY REACTIONS OF VIRUSES

*The Immunological Reactions of the Filterable Viruses.* By F. M. Burnet, E. V. Keogh and Dora Lush. (Pp. 368, 27 figures, 17 tables, 10s.) London: H. K. Lewis and Co. Ltd. 1937.

Dr. F. M. Burnet's contributions to the literature of filterable viruses are both numerous and valuable and to these he has now added a monograph on the immunological reactions of viruses. In this last work he has had the collaboration of E. V. Keogh and Dora Lush both of whom have been working with Dr. Burnet at the Walter and Eliza Hall Institute of Medical Research since he returned to Melbourne. While in this country much of Burnet's work was concerned with the bacteriophages and more particularly their neutralization by means of antisera: their antigenic structure and their mode of action with the susceptible bacteria. An earlier chapter in the present monograph deals with this work on the immunological reactions of the bacteriophages and the authors show that despite certain superficial differences due to the small size of these phages there is no real difference between the behaviour of phages and bacteria in these

reactions. It is of interest to note that they are of the opinion that the bacteriophages, like the viruses generally, can most usefully be considered as minute living micro-organisms. The study of the neutralization reactions of the phages has been more readily and accurately studied in the past than similar reactions with the filterable viruses because the methods available for phage titration are relatively accurate and easily carried out. The titration of viruses in the living animal is, at the best, somewhat inexact. As Burnet has shown, however, the chorio-allantoic membrane of the developing egg provides a means of virus titration of much greater accuracy than the animal, and he and his colleagues in Melbourne have made use of this method in the investigation of a number of animal viruses and their antisera.

Having considered the immunological reactions of plant viruses and devoted a chapter to some general considerations concerning animal viruses and their antisera, they describe in successive chapters the neutralization reaction of a number of representative viruses as studied by the egg technique. As in the case of the bacteriophages, differences between the behaviour of viruses and bacteria are noted, though here again they are considered to be only superficial. The lack of firmness of union between virus and antibody, noted by previous workers in this field, is confirmed and the reason for this is discussed. It is shown that the percentage law, discovered by Andrewes and Elford in the case of the bacteriophages, holds also in the case of viruses, the reason for this being the relatively enormous amount of antibody to antigen in the neutralization reaction over a large range of antiserum dilutions.

In the concluding chapters of this valuable monograph the authors take up such questions as the consideration of virus immunity from the biological point of view, the site of formation of virus antibodies, and the production of active immunity against virus infections. Concerning this last problem, the use of living attenuated virus is held to be the method most likely to give success, the employment of killed virus being considered of little use for this purpose. Though in the main such a conclusion will meet with general acceptance, it is perhaps rather sweeping and overlooks the fact that killed vaccines have been shown to be of value in the case of some viruses at any rate.

### Notes on Books

In *Mortality Trends in Minnesota* (Oxford University Press, 16s.) Professor CALVIN F. SCHMID sets out in a convenient form the mortality experience of the State of Minnesota from 1910 to 1935. The population of the State was 2.1 millions in 1910 and 2.6 millions in 1930, in 1910 41 per cent of the population lived in urban sections, in 1930 this proportion had increased to 49 per cent. Trends of mortality from the principal causes are shown and a succinct discussion of possible factors is provided.

For the French series of new treatments Dr F. RATHERY has produced an excellent practical little book on the insulin treatment of diabetes. He stresses the fact that in severe cases (diabetic coma) insulin is the only treatment of any use. He gives clear indications on how to start it and work out the best individual dosage for each patient. The theoretical aspects of insulin resistance and sensitivity are discussed in great detail. The proinsulin compounds should have received more mention. The full title of the book is *La Pratique de la Cure Insulinique et les Diabétiques (en dehors des grandes complications)* and it is published in Paris by J-B Baillière (price 25 fr.).

## Preparations and Appliances

### PLASTER FORCEPS

Mr A. ANDERSON BONAR F.R.C.S.  
Ed (Ashington, Northumberland),  
writes

Having watched nurses and others struggling with a thick plaster in an attempt to remove it, I devised a form of forceps, shown in the accompanying illustration. The plaster is split along one side in the usual way with Lorenz's shears. If the plaster is thin removal involves no difficulty. In thick plasters—for example hip spica plasters and in certain walking plasters—it may be a matter of difficulty to remove them without causing extreme discomfort, and even pain, to the patient. The forceps shown here largely overcomes these difficulties. It is simple in design, easy to handle, and the method of application is obvious.

The Medical Supply Association has made this forceps for me, and I have pleasure in acknowledging their help.

### VISIBLE BOOK-KEEPING AND CASE-RECORDING

H. K. Lewis and Co. Ltd. have produced a new loose leaf system for medical book keeping and case recording which seems to reduce the labour involved in both these necessary and complicated tasks to a minimum. This new device is a steel-spined ledger with the usual projecting signals in evidence so that it may be opened at any letter of the alphabet. Once opened the names of twenty-five patients are immediately visible in each section, every name being at the bottom—or on the other side at the top—of overlapping sheets (5 inches by 8 inches) adequate for any ordinary clinical history, and having appropriate spaces for such necessary details as the patient's age, sex, occupation, civil state, and so on. For the recording of clinical histories this method would seem to combine all the advantages of the case book and the card index. The loose leaves for book keeping are similar in size and in overlapping arrangement, but the space allowed for clinical histories on the companion leaves is taken up in the book keeping section by all that is necessary for the recording of visits and consultations. There are ruled columns sufficient for a record of one visit on every day of the year in the case of any one patient. Should the patient survive this a new leaf will have to be inserted for his benefit but if his demands are less exacting the same sheet may last—with the patient—for as long as twelve years. There are also the necessary columns for the total fees payable in each month, the date on which the account was sent, the amount due, and the amount received. The leaves of both varieties are perforated and may be inserted—after a little practice—at the required level on chromium plated rings, all of which open at the turn of a wing nut set in the steel spine.

The complete outfit with 300 sheets costs £2 18s. 6d. or with 500 sheets £3. The binders which seem so solidly constructed as to be almost indestructible, may be bought separately or may the sheets for case notes, book keeping, or both from Messrs H. K. Lewis at 136 Gower Street, London, W.C1. It is perhaps a sign of the times that there is a space for the patient's telephone number beneath the column headed 'Amount Due'.

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY MAY 28 1938

## FEVER THERAPY

Pyretotherapy can be active as when a febrile attack is produced by the injection of a foreign substance usually a living organism or a protein or passive when fever is produced by physical means such as short waves or a warm humidified atmosphere. The methods are not identical and it is possible to have shock therapy without fever. The monograph on this subject edited by Dr Walter M. Simpson and Dr William Bierman is a compilation of abstracts and discussions of papers presented at the first International Conference on Fever Therapy in New York in March 1937.<sup>1</sup> Fever is one of the weapons which warm blooded animals, and particularly mammals use to counteract the attacks of parasitic micro-organisms and early experience taught the benefit of very hot baths and other means of external heating. The demonstration of hyperpyrexia produced by physical agents however was not made until 1883. Philipps's original observations were repeated independently by Hill and Flack in 1908; they showed that the temperature of the body could be raised even up to 103° F. by means of hot baths. Dr Clarence E. Neymann has collected and has summarized the available data on artificial fever produced by physical means.<sup>2</sup> His own specialty—psychiatry—has been the means of greatly contributing to knowledge of the subject. As early as 1876 Rozenblum of Odessa purposely inoculated psychotic patients with relapsing fever and published the favourable results he observed after these and other psychotic and demented patients had recovered from relapsing fever, malaria and typhus. Much later infection with malaria relapsing fever the injection of tuberculin, typhoid vaccine, suspensions of sulphur in oil and other organic and inorganic compounds came into vogue and were successfully used in the treatment of general paresis. The common factor in all these remedies is fever.

Many of the sequelae following hyperpyrexia such as nausea, vomiting and prostration are apparently due to disturbance in the patient's fluid

and chloride balance. They can be mitigated by giving large amounts of chloride containing fluid before, during and after the treatment and by increasing the relative humidity and decreasing the dry bulb temperature of the atmosphere to which the patient is exposed. The pathological changes following fever therapy are summarized as engorgement of the blood vessels especially of the capillaries associated with haemorrhage of varying extent and necrosis of the tissues including the muscles, liver, kidneys, lungs, adrenals and brain. Haemorrhages and patchy necrosis in the central nervous system are striking and consistent findings especially where the sedative used was a respiratory depressant. Fever therapy is therefore a dangerous remedy and it should be used only by the expert and for the seriously ill. Its curative action is unexplained though two important factors appear to be weakening of the virulence of infecting organisms and the stimulation of phagocytic cells in the tissues. The greatest triumphs of pyretotherapy have been in the venereal diseases although there are but few conditions in which success has not been claimed for fever therapy. It has been much employed in vascular lesions in acute and chronic rheumatism and chorea and in the various forms of paralysis. The disappearance of tumours after neighbouring infections such as erysipelas or cellulitis is well established and has sometimes been successfully copied by the use of Coley's fluid. Both local and general fever have occasionally been used successfully in malignant disease and it appears that the cumulative effects of fever and x-rays are superior to either alone. There is no proof that a febrile disease can be aborted by an early application of artificial fever but certain chronic diseases both febrile and afebrile can be cured by this means. Penetrating heat appears to be more efficacious than external heat and all other factors being equal electro-pyrexia produced by high frequency electrical currents, damped or undamped is the method of choice. Reliance should be placed only on the rectal temperature; a benzol fused quartz thermometer should be used. In an air-conditioned cabinet in conjunction with electromagnetic induction temperatures of 106°–107° F. or more may be attained.

It is perhaps in dementia paralytica that the results of pyretotherapy are most established. Kraepelin compiled a series of 3,079 cases of paresis treated with malaria. He concluded that 1,319 showed some improvement; this is approximately 43 per cent. About half this number achieved a full remission; 57 per cent did not improve while during and just following the course of treatment with malaria the death rate ranges between 10 and

*Fever Therapy: Abstracts and Discussions of Papers Presented at the First International Conference on Fever Therapy.* New York: Paul B. Hoeber Incorporated Medical Book Department of Harper and Brothers. (5 dollars).  
*Artificial Fever Produced by Physical Means: Its Development and Application.* By Clarence A. Neymann, M.D. London: Baillière Tindall and Cox. (27s.).

30 per cent Since the spontaneous remission rate of dementia paralytica is less than 4 per cent, it is clear that the introduction of malarial therapy was a great step forward, even if the death rate is fairly high A total of 979 cases treated by electropyrexia has been collected by Dr Neymann from published results Of this number 27 per cent are credited with a complete remission, and a further 36 per cent are reported as improved and said to be no longer in need of hospital treatment Thus electropyrexia has increased the total rate of improvement by 20 per cent, while those who have died as a direct result of treatment amount to only 2 per cent In treatment at least eight hours of continuous body temperature above  $103.5^{\circ}\text{F}$  should be employed, and during at least two of these eight hours the temperature should range slightly above  $105.8^{\circ}\text{F}$  Usually the bouts of fever should be given twice a week and the course of treatment continued until a mental recovery results A patient should not be abandoned as hopeless until he has received fifty treatments Tryparsamide and heavy metals should be given with the electropyrexia In syphilis of the nervous system electropyrexia appears to be of some avail—not, of course, in restoring nerve paths and fibres already degenerated In tabes much alleviation of lancinating pains and crises has been obtained Artificial fever alone will not eradicate the syphilitic virus even if body temperatures are maintained that are more than adequate to kill cultures of the *Treponema pallidum* in the test-tube, chemotherapy is needed Electropyrexia has opened a new approach in the treatment of all forms of gonorrhoea Each individual strain of gonococcus appears to have a thermal death time which ranges from five to twenty hours at  $106.7^{\circ}\text{F}$  Usually three-quarters of the number of hours established as the thermal death time *in vitro* is sufficient to eliminate the gonococci from the human system, about 15 per cent of all cases, however are not helped by electropyrexia The location of the gonorrhoeal lesion appears to make no difference Arthritis, ophthalmitis, urethritis, and salpingitis are cured in an identical manner

On the effect of electropyrexia in other diseases little definite has been attained, but Dr Neymann is of opinion that Sydenham's chorea is promptly aborted in the vast majority of cases The method is not contraindicated in rheumatic carditis complicating chorea If anything this condition is ameliorated by bouts of artificial fever Arthritis is another disease in which treatment by electropyrexia has proved a great aid The cases must be selected, as the hypertrophic form does not respond well and the patient may even be harmed by this treatment All the well-known forms of

treatment—rest, elimination of focal infections, physiotherapy of various sorts—must be employed, in chronic refractory atrophic arthritis electropyrexia has a place In the non specific therapy of asthma electropyrexia is useful It has been tried in a host of other chronic diseases, many of which will never yield to pyretotherapy Dr Neymann makes a strong case for its use in specified diseases and has endeavoured to lay down the indications

## THE PLANNING OF MATERNITY HOSPITALS

The annotation under the above heading (April 30, p 955), to which exception has been taken in our correspondence columns, was elicited by a paper read to the Royal Sanitary Institute by Dr Thomas Orr, medical officer of health for the borough of Ealing In this paper the author quoted a recommendation made by the Departmental Committee on Maternal Mortality and Morbidity in 1932 as follows "In the interests of economy as well as to facilitate specialist treatment of non obstetric conditions associated with pregnancy and childbirth, new maternity accommodation should, where practicable, be associated with general hospitals" With this recommendation Dr Orr found it "difficult to agree entirely" and stated "two very strong arguments in favour of an entirely separate institution" The first argument is that the normal maternity patient is not a sick woman and therefore she need not be sent to a general hospital The second is that "there must be separate domiciliary accommodation for the nursing staff attending maternity cases" In illustration of his first point Dr Orr quoted the case of a maternity hospital dealing with over 500 cases a year in which "it was not found necessary, over a period of four years, to call in a medical or surgical consultant on any occasion" With Dr Orr's contentions so far we are entirely in agreement Dr Henry H MacWilliam, in supporting the recommendation of the Departmental Committee in his letter published on May 14, appears to have overlooked certain important considerations (a) that the great bulk of the work of a maternity hospital consists of the care of women who are in good general health, and rated, from the obstetric standpoint, as "normal cases", (b) that the medical and surgical complications of pregnancy and labour are relatively uncommon, and that the principal special maternity hospitals number among the members of their honorary staffs representatives of medicine, surgery, paediatrics, and ophthalmic surgery, (c) that the emergencies which occur in a maternity hospital are

obstetrical not medical or surgical emergencies (d) that the post mortem examinations in a maternity hospital are not really as he supposes carried out by members of the obstetric staff (e) that cases of puerperal sepsis are not offered the best chance of recovery by being admitted to a medical unit.

A further consideration should be borne in mind. The Departmental Committee advised that to provide the optimum of safety a maternity unit should contain fifty to sixty lying-in beds and five to ten ante-natal beds and should deal with 800 to 1,000 cases a year. How many general hospitals in this country can provide a maternity unit of that size? And further is it reasonable to expect that they will be able to do so? An unsatisfactory feature of the present obstetric position is the insignificant size of the maternity units of most of our important general hospitals including the teaching hospitals. We believe that if the first-quoted recommendation of the Departmental Committee were fully carried out the result would be the eventual disappearance of special maternity hospitals. By common consent the present accommodation for maternity cases is inadequate and considerable increases must before long be undertaken. The Committee desired that the additional new accommodation should be provided in connexion with general hospitals *where practicable*. These qualifying words have really no significance for a general hospital is an independent organization which will be its own judge of what is practicable. In consequence the prospect before us would be that the special hospitals would be unable to participate fully either in the coming extension of midwifery accommodation or in the advances and improvements in hospital construction which the future will bring. These hospitals would first suffer in efficiency and finally perish of inanition. We cannot think that our correspondents would wish to see this result brought about.

It is not too much to claim that the special maternity hospitals of this country are in the van of obstetric teaching and practice and certain of them can hold their own even with Professor F. J. Browne's department at University College Hospital or the more recently established unit at the Postgraduate Hospital under Professor James Young. Has the work recently done at Queen Charlotte's Hospital by Drs. Colebrook and Fry and the other members of their research team been overlooked by our correspondents? Thanks to the generosity of British and American donors and thanks also to the courage and enterprise of its board of management Queen Charlotte's Hospital has built up a research organization which is unsurpassed in the obstetric field. Has the maternity unit of any general hospital done better? Why,

then should the special hospitals be shouldered out? It is not questioned that provision for maternity cases is required in many general hospitals to meet local requirements and to complete the equipment of teaching hospitals. Our submission is however that the special maternity hospitals are playing a most important part in obstetric teaching and practice and that it would be a national disservice to weaken their position from ideological considerations.

### THE B.M.A. BUILDING AND THE ROYAL ACADEMY

Not only members of the British Medical Association but also others both medical and lay have learned with interest of the inclusion in the 1938 Royal Academy Exhibition of the architect's plans for the completion of the building scheme adopted some years ago by the Association. These plans prepared for the Council by Mr. Douglas Wood, F.R.I.B.A., are the subject of an article in this week's *Supplement* by the Chairman of the Building Committee, Dr. Henry Robinson, and in the middle of the *Supplement* there is reproduced a drawing by Mr. Wood representing the exterior of the finished building as seen from Tavistock Square. Everyone must judge for himself of the merits of this ambitious plan; to us it seems wholly admirable and it is satisfactory to find what is of course merely a lay view of an artistic matter confirmed by the verdict of Mr. Douglas Wood's colleagues in his own profession and by the Council of the Royal Academy. Mr. Wood and the British Medical Association are alike to be congratulated on a plan which will produce a real addition to the architecture of London.

### A COURSE IN MEDICAL HISTORY

For the first time certainly in the United States of America and possibly in the world a graduate course has been devoted to the history of medicine. That stimulating scholar and philosopher, Henry Ernst Sigerist, Welch Professor of the History of Medicine at the Johns Hopkins University and Director of its Institute, through a carefully planned programme brought together at Baltimore during the week of April 18 to 23 a large and enthusiastic group of men and women from the United States and from Canada among whom were a number of distinguished historians. The President of the University, Dr. Isaiah Bowman, opened the proceedings. The morning sessions were devoted to lectures and discussions and included such topics as principles of primitive medicine, Egyptian medical papyri, the Hippocratic problem, Paracelsus and the development of iatrochemistry, new contributions to the history of the circulation of the blood and the social history of medicine in the nineteenth century. In the informal atmosphere of the afternoons round-table seminars attention was primarily focused on

problems concerning teachers of medical history, such as the various approaches to its study, the interpretation of medical texts, the history of disease, and the choice of a subject for research. The more strenuously educational part of the course was skilfully mollified and at the same time enhanced by exhibits, visits to libraries and learned societies, cocktail parties, and dinners. The vast armamentarium of research and equipment which the Institute commands was made available to those desirous of learning for themselves how medical history may be pursued as an exact scientific study and how it may also be temptingly and successfully introduced into medicine's daily work. Just as in international congresses, one of the more valuable aspects of this graduate week also was the opportunity it afforded of meeting kindred spirits and of discussing individual problems with Dr Sigerist and his staff, who freely gave their undivided attention. The most original item on a crowded programme was a musical evening in the Great Hall of the Welch Medical Library, which houses the Sargent Portrait of the Four Professors. Four string instruments and one soloist performed music which had not been heard for two or three centuries—a frottola on the syphilis of Marchese Francesco Gonzaga of Mantua (1517), dance music played in Southern Italy during the seventeenth century in the treatment of that astonishing disease tarantism, and hymnlike music in praise of St Sebastian, patron saint against the plague (1702). Intended purely as an experiment, this graduate course was by common consent so helpful and so delightful that it will be repeated in future years and should become a recognized feature of medical education in America and possibly also in other countries.

### AN INTERNATIONAL SURVEY OF BLINDNESS

The International Association for the Prevention of Blindness has published a long report dealing with *The Number of the Blind and the Protection of the Eyes in Different Countries*<sup>1</sup>. The International Association was founded at The Hague in 1929. Since then it has carried out useful inquiries on the incidence of various blinding diseases of the eyes and on methods of prevention. The present volume is the result of its most ambitious effort. A questionnaire was issued to all the countries of the world two years ago. Replies were received from thirty-five. The book gives a correlation of these replies. Some countries gave official replies, others answered through individual societies or oculists and further data were supplied by the League of Nations. The report shows how largely the incidence of blindness is a social and economic problem. Prevention of blindness is in the main to be secured by improvements in general hygiene, and that depends upon the social habits of the peoples. In highly industrialized countries there are the added risks of injuries which need to be guarded against. This survey sets out what is being done in the several countries which have furnished information. It is a distinctly instructive record and

since it is issued in an English edition it is available for all those in the worldwide English-speaking countries who take an interest in the matter. It shows what a great need there is for some sort of common agreement in the various countries as to the definition of blindness and the manner of recording statistics, and also for some adjustment of the returns according to the social relief granted to the blind. In some countries no relief is given and the number of blind recorded is small. In other countries, such as Britain, the blind are treated most generously and the number registered is high. The great variation of the incidence of the various forms of blindness is best illustrated by trachoma. This is rare in Western countries and very common and highly damaging to sight in Eastern countries. Myopia as a cause of blindness is much discussed by ophthalmic surgeons and educationists. The variations in the incidence shown in the returns are great. Twenty countries give no figures, though some of these state that they have "sight-saving classes" for children so affected—for example, Portugal, Switzerland, Lithuania, and Japan. Madagascar says definitely there is no high myopia there. Of the countries or cities that give figures the following is the list with the percentages attached: Scotland 17, London 13.93, Australia 13.5, Holland 13.2, France 8, USA 5.3, Tasmania 5.29, Germany 5.13, Rumania 2, Greece 1, Bulgaria 0.81. The differences in Great Britain alone call for some explanation. Those for Scotland are the figures gathered by Smith and Marshall (17 per cent), for London those of Bishop Harman (13.93 per cent), while those from Birmingham collected by Matthew Burn show 4.4 per cent. This report of the International Association will make a strong appeal to ophthalmologists and educationists interested in the care of the blind, and to social workers and members of statutory authorities who are responsible for supervision of the beneficent measures designed for the prevention of blindness and the amelioration of the hard lot of the blind. Its production merits high praise and credit for the staff who have worked so long and diligently to produce it.

### SIGNIFICANCE OF MOLES ON THE FACE

It has recently been suggested by E. Sklarz<sup>1</sup> that many of the small hairy moles and fibromata commonly met with on the face and neck are really rudimentary sensory organs and are analogous to the sensory hairs or whiskers of such mammals as cats, dogs, and rats. The chain of reasoning which led Dr Sklarz to this conclusion is quite interesting. He noticed that in rats which had been epilated by a sublethal dose of thallium the whiskers or sensory hairs persisted. The survival of the hairs is due to the fact that they derive their innervation from the cerebrospinal system, while the ordinary hairs which form the animal's coat are innervated from the sympathetic system. Thallium being a poison primarily affecting the endocrine glands and through them the sympathetic nervous system affects the ordinary hairs, but the sensory hairs escape.

<sup>1</sup> *The Number of the Blind and the Protection of the Eyes in Different Countries*. Paris (6c) 66. Boulevard Saint Michel.

<sup>1</sup> *Derm. Wschr.* 1938, 82, 462.

Thallium of course is not given to human adults so we do not know from direct observation whether the hairs on moles would escape its action. But in severe cases of alopecia areata (a condition in which the sympathetic system is affected) in which all the hair is lost it has been observed that hairs growing from moles remain. This suggests that they are innervated like the sensory hairs of lower mammals from the cerebro-spinal system and hence come into line with sensory organs in general. Now these sensory hairs in the lower animals are characterized by being placed on a special prominence which may be described as a wart or papilla. They are symmetrical and the root of the hair is always in connexion with a dilated blood vessel so that they have been called sinus hairs. There is always pigmentation. Now the moles often found on the face show certain points of resemblance both in situation and in their microscopical structure to the sensory warts or prominences of lower animals. Their commonest situation is on the cheek at a point corresponding roughly with that of the whiskers of cats and dogs and they are often more or less symmetrically placed. Microscopically the human mole like the sensory prominences of the animals is often pigmented. It is true that notwithstanding prolonged search through several hundreds of serial sections Dr Sklarz has not succeeded in discovering any blood sinuses in connexion with the hairs on moles but he has succeeded in finding certain structures in them close to the epidermis which he considers have a resemblance to sensory epithelial organs. They consist of round or oval enclosed bodies sometimes pigmented sometimes not possessing a definite capsule and in general suggesting the structure of an end organ in connexion with a sensory nerve. It would indeed be of great value in the examination of this question to be able to study the innervation of these bodies with the aid of special nerve staining methods. Much light might thereby be thrown on the theory that these encapsulated bodies are rudimentary sense organs. This however Sklarz has been unable to do owing to the difficulty of obtaining enough material. It must be remembered that there are distinct objections to the removal of any considerable sized piece of skin from the face. Nevertheless although much further research is necessary to afford definite proof that moles and fibromata (*Gesichtsnaevi*) are really rudimentary sense organs there is at all events evidence that this interesting and intriguing idea is reasonable.

### THE SUBNORMAL PRISONER

Criminologists are familiar with various grades of mental disorder and mental deficiency in prisoners and are making rapid progress in their appreciation of the psychological factors in crime. There is also however another class of person who seems to be fairly well recognized abroad but not to have attracted much attention here. That is the offender who is neither mentally disordered nor mentally defective nor even appreciably neurotic but merely subnormal. He is below par in every part of his personality—moral, mental and

physical. One might say that he is only partly alive. Many such people seem to drift into petty crime simply from the lack of sufficient nous to keep them out of it. Dr Norwood East, Medical Commissioner of Prisons, makes some interesting remarks on this group in the Commissioners' annual report. He says it includes criminals of inferior intelligence who are not classifiable with the mentally defective and cannot be certified as such. He calls them the constitutional psychic inferiority subgroup and regards them as important in the study of recidivism. Some of them are aggressive criminals and a menace to society but many are no more than a nuisance and in prison are quiet, well behaved, sensible and often rather likeable individuals. Both types present one distinguishing feature: they will soon return to prison after they have been released. An illuminating case who is melancholy, career Dr East summarizes is that of a man of 74 whose previous convictions started early in 1872 and now number about fifty. This is not the total of his offences for some may have escaped detection and others have been taken into account on remission at various times. The family history was uneventful and there was no insanity though a brother had been in prison. At the age of 17 when he was sent off five years penal servitude for pocket picking he had already formed a criminal habit. At a recent interview Dr East found him intelligent, alert and without enmity to society. He has kept in touch with his relations and is welcomed by them on release. He is well preserved physically and mentally and is on the whole an optimist. He gives no trouble when in custody, is satisfied and contented and may, be to a certain extent institutionalized. He is a man whose dispositions and temperament work best in low gear. He has had little ambition and has derived little satisfaction from success and suffered little disappointment from failure. Dr East might agree that his habit of returning to prison at short intervals is perhaps the best adaptation to life of which he is capable that he cannot stand alone and that the nearest substitute for a parent he can find is His Majesty's prison. Dr East finds the aggressive type of recidivist not so common as the passive. He lays stress on the experience that rather of these subnormal types is likely to respond to psychological treatment after they have had a number of convictions and thinks that the detention establishments suggested by the Persistent Offenders Committee may well prove eventually to be a more humane and logical method of dealing with them. Psychotherapy like the steering gear of a ship will only work if there is some propulsive force in operation. The best way of dealing with these people may be to regard them as necessarily permanent inmates of an institution or colony just as many mental defectives are. Incidentally Dr East gives a wide survey of the limitations of psychological treatment. If this method is to be of lasting value the claims made by its exponents must constantly be subjected to the criticism of practical experience. That is far more likely to bring it to general use than any amount of propaganda.

## ROYAL SOCIETY CONVERSAZIONE

The Royal Society conversazione last week again brought together an interesting assemblage of exhibits illustrating advanced work in many fields. Special interest attached to the new methods of sampling industrial dusts, shown by Professor H. V. A. Briscoe of the Royal School of Mines, who has lately received the gold medal of the Institution of Mining and Metallurgy for this work. The latest method which Professor Briscoe has elaborated is called the labyrinth, and consists of an assembly of baffles in a conduit through which the dusty air is drawn. This enables relatively large samples to be collected for chemical analysis, solubility determinations and physiological experiments. The idea has been to establish the causative agent or property responsible for silicosis. Mr. J. E. Barnard showed a simplified method of ultra-violet light microscopy. The greatest obstacle to the wider use of ultra-violet light in microscopy is the need for somewhat elaborate electrical apparatus to produce a high-tension spark of sufficient intensity. This is now in part overcome by using a mercury vapour discharge lamp of special pattern. A large part of the ultra violet energy produced by this lamp is confined to one line of a particular wave-length which is useful in investigations with fresh biological material especially when the presence of a virus is suspected. Some of the historical exhibits were of not less interest than the products of modern laboratories. There was shown for example an original crayon drawing of the physical laboratory of the Academy of Sciences of Paris in the early eighteenth century, the work of Sebastian Leclerc, who was not only an accomplished artist but had applied himself to the study of physics and therefore was able to depict the various scientific instruments, of which more than one hundred were shown, with a fidelity which no one before, or since has achieved. Another exhibit of historical interest which has just come into the possession of the Science Museum was John Hadley's original Gregorian reflecting telescope. Hadley was also famous as the inventor of the reflecting sextant. Another exhibit was obtained from the sale of Isaac Newton manuscripts not long ago in the shape of the earliest trade card of an English optician. It bears the name of John Yarwell and the date 1683 and the back is covered with extracts from the classics in Newton's writing. To turn from these old excursions to very modern instances the Cambridge Psychological Laboratory had an exhibit one part of which was designed to illustrate the factors influencing sensory thresholds. The effect of sensory adaptation was shown on visual acuity, brightness discrimination and loudness discrimination. An apparatus was demonstrated with which the eye can be adapted to any illumination from 0 to 45 000 foot-candles and visual acuity rapidly measured at any illumination over the same range. Another exhibit showed the effect of the rate of application of a stimulus. If the intensity of a stimulus be increased the amount of increase necessary to give rise to a perception of this change is dependent upon the rate at which the change is made. In touch pressure sound, and light—in fact, in all the

cases studied with the exception of that of pain—a decided fall in the threshold is found with increase in the rate of application of the stimulus. Yet another exhibit from the same laboratory showed the effect of knowledge of results on learning and performance. The experiments showed that improvement in performance occurs only when the knowledge of results is afforded. After a fairly high standard of performance—in this case a relatively simple muscular movement—removal of knowledge of results leads to a very pronounced deterioration—which, as with many of these results of psychological experiment, is just what we should expect.

## LISTER MEDAL

The Lister Medal for 1939, which is awarded in recognition of distinguished contributions to surgical science, has been granted to Professor Rene Leriche, professor of clinical surgery in the University of Strasbourg, and he will deliver the Lister Memorial Lecture in 1939 at the Royal College of Surgeons of England. This is the sixth occasion of the award, which is made by a committee representative of the Royal Society, the Royal College of Surgeons of England, the Royal College of Surgeons in Ireland, the University of Edinburgh, and the University of Glasgow. Previous Lister medallists have been Sir William Watson Cheyne, Professor Anton von Eiselsberg, Professor Harvey Cushing, Sir Charles Ballance, and Sir Robert Muir.

## PAGET MEMORIAL LECTURE

The twelfth Stephen Paget Memorial Lecture, on 'Insulin and Diabetes: The Present Position,' will be delivered by Professor Charles H. Best, M.D., D.Sc., of Toronto University, at the annual general meeting of the Research Defence Society at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C., on Thursday, June 9, at 3 p.m. The chair will be taken by the president of the Society, Lord Lamington, supported by Sir Arthur Stanley, chairman of committee, Sir Edward Mellanby, F.R.S., vice president, and Professor A. V. Hill, F.R.S., vice chairman of committee. Tea and coffee will be served after the meeting, and visitors will be welcomed.

The eighty-ninth annual session of the American Medical Association will be held in San Francisco from June 13 to 17. The scientific sections number fifteen this year.

On May 19 Professor J. J. Abel, director of the laboratory for endocrine research at the Johns Hopkins Medical School, Baltimore, was elected a Foreign Member of the Royal Society.

# SURGICAL PROCEDURES IN GENERAL PRACTICE

*This is one of a series of articles contributed by invitation*

## SOME NASAL CONDITIONS

BY

E D D DAVIS, F.R.C.S.

### Nasal Polyp

Nasal polypi are localized areas of oedema of the mucosa of the ethmoid and more commonly the external or meatal surface of the middle turbinal. The polypi arise from the narrow upper part of the nose and as they increase in size they expand to the more spacious and broader part hence becoming pedunculated. Nasal polypi are divided into three main groups according to their aetiology (1) allergic (2) allergic with secondary infection (3) infective or inflammatory.

The allergic group is the commonest and is associated with allergic vasomotor rhinorrhoea of long duration. There is a family history of allergic manifestations such as asthma hay fever and urticaria. The nose shows the characteristic and variable pale moist swelling of the mucosa, and the patient has attacks of nasal obstruction sneezing and rhinorrhoea similar to hay fever. The polypi frequently recur in spite of vigorous treatment. Mucus is retained in the nasal sinuses and a low grade infection is not uncommon.

The infective or inflammatory polypi accompany a chronic rhinitis or sinusitis. X ray photographs should be obtained since they are always useful. There is an uncommon type of single polypus known as the post-nasal or choanal polyp which starts in the middle meatus of the nose and extends backwards into the posterior nares and nasopharynx. It occurs in young subjects and has a long stalk attached to the mucosa of the antrum just within the ostium. This large polypus blocks the posterior nares hence the marked nasal obstruction and if it is completely removed it may not recur for some years.

### DIAGNOSIS

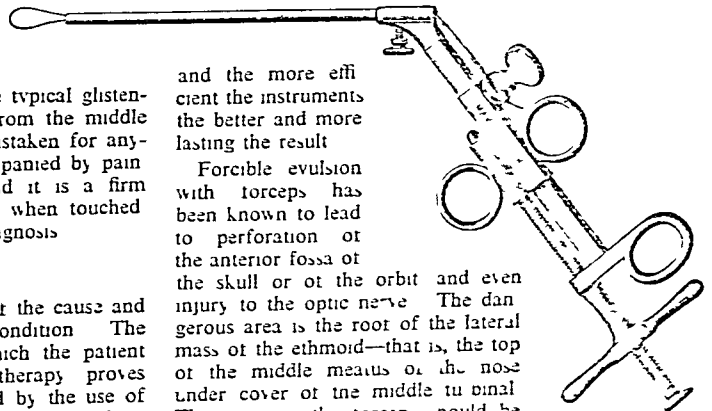

A good view of the nose will show the typical glistening polypi like muscatel grapes arising from the middle turbinal region. Polypi can hardly be mistaken for anything else. A malignant growth is accompanied by pain it occurs in patients of cancer age, and it is a firm vascular red tumour which bleeds freely when touched. Microscopical section will confirm the diagnosis.

### TREATMENT

This must be directed to the removal of the cause and particularly to the underlying allergic condition. The elimination of the exciting causes to which the patient is sensitive with calcium and thyroid therapy proves successful. Little or no relief is obtained by the use of sprays lotions and inhalations. In fact these applications are irritating. Immediate relief can be obtained by removing the polyp with the snare under cocaine anaesthesia. Polypi will recur at varying intervals but the more thorough the removal the less frequent the recurrence and in the case of the single polyp a long interval of freedom is probable. Though removal by snare may be merely palliative it has the advantage of allowing a

clear inspection of the interior of the nose at a later date. On the other hand when the polypi are multiple and inaccessible to the snare and if sinus suppuration is present a more radical operation under general anaesthesia is required. The radical operation consists in removing the polypoid middle turbinal and the parts of the ethmoid from which the polypi grow. It may be necessary to resect the nasal septum in order to obtain a free access to the polyp growing area. An suppurating nasal sinus is drained.

The snare operation is done when the patient is free from a cold or recent infection. He is placed in the sitting position and the best possible illumination is obtained by means of the forehead mirror or head lamp. Strict asepsis and antiseptics must be observed. The nose is anaesthetized by swabbing the mucosa of the affected area with a solution of equal quantities of 20 per cent cocaine and adrephine inhalant (Paine Davis). Adrenaline 1 in 1000 solution may be used instead of adrephine but adrenaline has the disadvantage of producing a reactionary and profuse rhinorrhoea sneezing and occasional bleeding an hour or so after its application. The nose is then gently packed with narrow ribbon gauze soaked in the solution of cocaine and adrephine. If a cocaine spray is used the solution should not be stronger than 4 per cent and the patient is directed to expectorate any of it which trickles into the throat. The snare is threaded with No. 3 snare wire and the orifice of its barrel should have a bridge so that the wire cannot be pulled right through into the barrel cutting off the polyp; it is thus avoided. The polyp is threaded through the snare loop and the barrel is firmly pushed up to their attachment. The polyp should be pulled off rather than cut so as to obtain an underlying flake of the ethmoid bone. The snaring operation should be done with a light hand and the better the technique

and the more efficient the instruments the better and more lasting the result.

Forceful evulsion with forceps has been known to lead to perforation of the anterior fossa of the skull or of the orbit and even injury to the optic nerve. The dangerous area is the roof of the lateral mass of the ethmoid—that is, the top of the middle meatus of the nose under cover of the middle turbinal. The point of the forceps should be used parallel to this area and not directed straight at the roof. Curetting with a sharp ring knife has resulted in severe haemorrhage and osteomyelitis. Rest in bed for a few days is necessary after any nasal operation exposing the ethmoidal infections is thus avoided. The nose should be left alone and at rest. Interference with the natural process of

Some of the polypi

healing, such as the use of sprays and lotions, is undesirable

If haemorrhage is excessive the patient should be kept in the sitting position. Injections of haemostatic serum and calcium may be given. A hypodermic injection of 1/4 grain of morphine for an adult is often more effective than any other remedy. If plugging the nose is really necessary, gauze soaked in the cocaine-adrephine solution mentioned above is gently packed on to the bleeding point. The gauze should be removed at the end of twelve hours. Prolonged packing leads to sepsis, a rise of temperature and tonsillitis are often the first indications of sepsis following a nasal operation. A careful inspection of the nose at the end of a fortnight should be made for polypi which have not been seen at the snaring operation. The treatment of allergic polypi by radium implantation is still on trial.

### Atrophic Rhinitis (Ozaena)

This is a chronic inflammation of the nasal mucosa which results in the loss of the ciliated epithelium and atrophy of the mucosa. The mucus dries, forming large offensive crusts which accelerate the atrophy of the mucosa. There is a loss of the sense of smell, and these patients are susceptible to any catarrhal infection. Patients with atrophic rhinitis are often found to have pulmonary tuberculosis, and a search for the tubercle bacillus should always be made. In severe cases the atrophy and crusting extend to the pharynx and the trachea.

#### DIAGNOSIS

The typical atrophy of the inferior turbinates with the easily recognized and unmistakable offensive odour of the crusts, the broad roomy nose and the long duration of the disease leave no doubt as to the diagnosis. There are a few cases of syphilis, with necrosis and perforation of the middle third of the septum, which may resemble atrophic rhinitis.

#### TREATMENT

The disease starts in childhood, and treatment should be early and continuous to prevent the later atrophic changes. It consists, first, of thorough cleansing of the nose and, secondly, the prevention of crusts. The nose is cleaned by large quantities of alkaline solution, such as equal parts of common salt, sodium bicarbonate, and boric acid one teaspoonful to a pint of warm water. The nose is irrigated with a large nasal irrigator such as Downs's quadruped nasal irrigator. Any adherent crusts should be removed by forceps or by swabbing with hydrogen peroxide. Crust formation is prevented by spraying the nose thoroughly with lipiodol or, if lipiodol is irritating, equal parts of lipiodol and paroline simplex (Burroughs Wellcome and Co). A mixture of potassium iodide 5 grains with aromatic spirit of ammonia 10 minims at intervals is helpful. The latter counteracts the depressing effect of the iodide. The first thorough cleansing should be performed under cocaine anaesthesia by the surgeon and the patient is shown how to use the lotion and spray. The nasal toilet consisting of lotion and spray should be carried out by the patient morning and evening but in the milder cases once daily, at night-time is sufficient. Treatment has to be continued for long periods and so long as there is any crusting or discharge. The general health should receive careful attention and residence at the seaside is beneficial.

### Foreign Bodies in the Nose

Young children push pieces of paper beads fruit-slices etc into the nose and these are found in the

atrium of the middle meatus. It is very easy to lose pieces of gauze or pledgets of cotton-wool in the nose during an operation. Foreign bodies may enter by way of the nasopharynx during swallowing or vomiting, particularly if there is any deficiency or loss of function of the soft palate. If the foreign body is allowed to remain for any length of time it will be covered with calcium deposited from the excessive nasal secretion and so form a rhinolith. A history of the foreign body having been introduced into the nose is not always obtainable, and it is only when ulceration and suppuration occur that attention is directed to that organ.

#### DIAGNOSIS

A blood stained offensive discharge from one nostril in a child points to a foreign body, and a close inspection of the nose after shrinkage of the mucosa with cocaine and adrephine will confirm the diagnosis.

#### TREATMENT

The nose is anaesthetized with cocaine-adrephine solution as used for nasal polypi and the patient is directed to blow the nose vigorously. This may produce the foreign body, but it also has the effect of clearing the nose of secretion. The foreign body is removed by means of a suitable looped hook or forceps, under direct vision with efficient illumination.

Looped hook used in removing a foreign body from the nose.

In difficult, frightened children and when the foreign body is far back in the nose a general anaesthetic is necessary. Syringing to recover the foreign body should never be done, as it may result in the substance being driven into the trachea or into an inaccessible part of the nose. Also, children are frightened by syringing, and infection may be driven to the Eustachian tube and ear.

E Fenz (*Munch med Wsch* March 4, 1938, p 323) describes the results of presacral infiltration with novocain in 143 cases of sciatica. After infiltration 112 were completely relieved, twenty-six were improved, and five showed no improvement. Seventy-six patients could be followed up for periods varying from six months to two years after treatment, forty-nine remained free of pain, sixteen remained improved, and in eleven recurrence had taken place. The technique adopted is described. The patient is fixed in the gynecological position. A thin needle 12 cm long is inserted along the inner side of the sacrum to the first or second sacral orifice, care must be taken not to damage the rectum. About 150 ccm of normal saline with 1/4 per cent novocain is then injected. The operation is painless except for the initial puncture of the skin. A single injection is often successful, but on the average four or five are required. The author has given as many as twenty-four without untoward results. Normal saline alone increased the pain. The addition of novocain is essential for success. The causative factor of sciatica could be determined in only 60 per cent of cases in spite of careful investigation. Of eighty-five cases the aetiological factor was found to be cold in twenty-four, intervertebral diseases in eleven, trauma in seven, diabetes in five, varicose veins in four, a tumour in one, nephrolithiasis in two, prostatitis in one and flat-foot in two cases. In 12 of sciatica although not always to the same degree. Even in diabetic cases the underlying cause was not treated in order to achieve a uniform result.

## PLANNING A HOSPITAL

### SIR HENRY GAUVAIN'S ORATION

In delivering the Annual Oration to the Medical Society of London on May 9 Sir HENRY GAUVAIN, medical superintendent of the Lord Mayor Treloar Cripples Hospital and College at Alton, Hampshire, took as his subject his experiences in connexion with the design of the hospital at Alton, with which task he was entrusted in association with a selected architect.

The patients at Alton said the lecturer were all crippled children, many of them tuberculous, requiring in most cases lengthy treatment and simultaneously needing education. It was early decided that the pavilion system should be adopted and that the ward units should be self-contained and adjacent to each other, with the exception of the isolation and observation blocks. This facilitated the transport of patients and was much safer for rapid evacuation in the unlikely event of fire. In planning an open air hospital one had not only to think of a ward but of the general layout and of the accessories indispensable for the work. At the Treloar Hospital the wards approached very closely to the ideal of the open air ward; they combined permanent structure and successful architectural treatment with maximum convenience and efficiency as well as maximum open air and light. The main hospital consisted of five ward units, each of sixty beds. Experience had shown that with the type of case treated one fully trained sister was able to supervise such a unit with the assistance of probationer nurses. The Board of Education had laid it down that thirty patients might be taught by one teacher and in order to earn most economically the educational grant for a hospital school the ward unit was divided into two similar parts, each half consisting of one large ward of twenty-four beds, one small four-bedded ward and two single-bedded cubicles.

#### Five ward Units at Alton

A tendency was apparent in modern hospitals, both for children and for adults, to abandon the large ward and replace it by numerous small wards or single or double-bedded rooms. In children's hospitals this had the alleged advantage of reducing the spread of infection. After much consideration he decided against this method at Alton, his chief reason being the need for ready and convenient supervision by a responsible person, which was so urgently necessary in the care of crippled children. To adopt the system of separate wards or cubicles would be inadvisable, not only on the ground of capital expense and maintenance, but also on that of staffing, having in view the increasing shortage of nurses.

The five ward units were erected on a great terrace 1,000 feet long and 25 feet wide. The terrace was paved with artificial stones set in a bitumen surround and impregnated with carborundum, which last was introduced to secure a non-slip surface. Green was selected as the colour to be restful to the eyes and avoid glare. In the centre of each ward unit was the sister's office and the patients in each of the large wards were under her immediate eye and she could also see what was going on in the small wards and cubicles. The ward walls to a height of four feet were of terrazzo with all angles rounded, while the centre flooring was teak. Heating was by panels in the terrazzo surround and in addition each ward was provided with an open fireplace, the psychological effect of a fire being very marked, especially on dull and dreary winter days. The whole of the south side of the wards, being open beds, were pushed out with the minimum of labour and it rained or snowed while the children were out, the sliding terrace roof of wired vitreous glass was lowered and instantly afforded the desired protection.

### The Treatment Centre

Sir Henry Gauvain went on to give some account of the design of the observation block and isolation hospital and then described what he called the heart of the institution—namely, the treatment centre. This was placed in a central position in relation to the ward blocks. There was a well-proportioned waiting hall from which direct access was obtained to the various departments—namely, operating theatre, x-ray room, plaster room, massage and exercise room and dispensary. Special attention had been given to the planning of the operating theatre, with all its adjuncts. The walls of the theatre were finished in pale green vitrolite and the floor was of terrazzo tiles polished after laying. The operating theatre and anaesthetic room were ventilated by an air conditioning plant on the roof. Great care had been taken with the electrical arrangements in the theatre area to prevent risk of fire or explosion. All plugs were interlocking and the switches were of the enclosed mercury sparkless pattern. An automatic record of air lighting system had been installed. The sterilizing equipment was of the most modern recessed type.

The patient left the theatre by a separate exit and the operation had been a major one, is transported to the adjoining recovery ward, coming in a room which was so planned that observation was easy. The massage and remedial exercise room, with about paneled walls containing heating panels, had a rubber paving to give good foothold for patients when taking walking and other exercises. The department opened on to a lawn where remedial exercises might be undertaken in the open air under favourable weather conditions. A bathing pool for remedial exercises was adjacent. It was a custom in shape thus permitting attendants to deal with patients without themselves getting into the water. The plaster room, specially designed for its work, had a buff tiled floor, tiled dado and painted plaster above. It was fitted with all necessary sinks and appliances, including allows for plaster spinal jackets and casts, special stands for hip and knee plasters and so forth. The dental room had a rubber floor and vitrolite wall linings. The x-ray room, studio, dark room and fireproof film store were in a suite entered from the waiting hall. This department was entirely shock proof and all wires within reach of the patient had been eliminated. A special type of radiographic table had been installed, fitted with two entirely shock proof tube holders.

#### The Light Department

There remained the light department, which purposefully he had not erected near the treatment centre. A number of the patients having light treatment were amputees and anyhow he felt that the treatment centre would be overcrowded by the constant stream of patients, some fifty or more a day, receiving light and allied treatments. Owing to the tall levels, one half of the hospital was two-storied; accordingly he had made the central portion of the lower floor into a covered winter playground, provided with radium heat and ultra-violet light, but quite open on its southern aspect. Behind this was the extensive light department, with sister's office and examination room.

I hope I have not wearied you, said Sir Henry Gauvain in conclusion, with this description of the hospital of my dreams, now completed and functioning satisfactorily for our needs. Doubtless in many ways it could be improved upon, but I am truly able to say I am content. If I may express a final thought on the most urgent need of modern hospitals, it is the lack of properly designed and protected balconies for accommodation. Realizing to appreciate that need one should be a patient as well as a doctor. The advantage of getting into the open air away from the sounds, sight and smells of the sick room must be experienced to be understood and in my opinion this is a factor insufficiently recognized in practice.

## Reports of Societies

### ANTERIOR HYPOPHYSIS IN DIABETES MELLITUS

At a meeting of the Section of Therapeutics and Pharmacology of the Royal Society of Medicine on May 10, Dr F. G. YOUNG gave details of some experimental work on the relationship of the anterior hypophysis to diabetes mellitus.

Dr Young said he thought his audience would agree that the theories as to the cause of diabetes were less complete and satisfactory to day than they were seven or eight years ago. There then seemed to be no serious doubt that the cause in the majority of cases of diabetes mellitus was a deficient secretion of the islets of Langerhans. There was some indication that the pituitary gland might sometimes be involved in the aetiology of diabetes, but it was generally agreed that the posterior rather than the anterior lobe of the gland was to be considered as responsible. Houssay's researches had undoubtedly provided the main stimulus for the vast amount of research which had taken place on the subject during the last few years. Houssay and a number of other investigators had almost simultaneously observed that the daily administration to intact normal animals of extracts of the anterior pituitary lobe might result in the appearance of symptoms of diabetes which, however, disappeared within a few days of the cessation of daily injections. This and other work suggested that hyperfunction of the anterior pituitary lobe as well as hypofunction of the pancreatic islets might be a cause of the symptoms of diabetes mellitus. In regard to the words "diabetes" and "diabetogenic," Dr Young explained that he meant by the former a condition in which hyperglycaemia, glycosuria, ketonuria, polydipsia, and polyuria were exhibited and the agent which provoked their appearance he described as "diabetogenic." The use of the term "diabetes mellitus" he restricted to diabetes in human beings. The majority of the investigations of which he gave details were concerned with the artificial production of diabetes in animals, and in this connexion Dr Young said that there was no proof that the results of the researches would throw light directly on the aetiology of human diabetes mellitus, though it seemed probable that they might ultimately do so.

#### Diabetogenic Extract of the Anterior Pituitary

He had found that dogs were by far the most satisfactory animals for demonstration of the diabetogenic activity of anterior pituitary extracts in intact animals. Cats and rabbits exhibited less striking and consistent results while rats and mice were comparatively insensitive. Extracts with diabetogenic activity were only slowly effective and it was only after two or three daily injections that hyperglycaemia and glycosuria appeared. If a dog was given a daily intraperitoneal injection of a suitable amount of a crude saline extract of fresh anterior pituitary gland there was usually no obvious result until the third or fourth day when hyperglycaemia was exhibited, the volume of urine increased and sugar and ketone appeared in the urine. If the daily administration of the same amount of extract was continued for seven to ten days the glycosuria and ketonuria—rarely the polyuria—subsided and finally disappeared. If the amount of extract injected daily was then suitably increased hyperglycaemia, glycosuria and ketonuria reappeared, only to disappear again with continued daily administration of the diabetogenic extract. The discovery of this phenomenon suggested that if the amount of extract

injected was increased suitably at intervals of three days the animal should remain constantly diabetic. This proved to be so. An important question then arose. If the amount of extract injected daily were increased to a very high level would the dog become completely resistant to the diabetogenic action of the extract? Or would the animal lose its power of becoming resistant? The latter proved to be the answer. All except one of the animals investigated had been found to be incapable of resisting the diabetogenic action of a daily dose of crude extract equivalent to 25 grammes of fresh tissue. Moreover, in these animals when the daily injections ceased the diabetic condition continued and had apparently become permanent. Thus treatment with the anterior pituitary extract appeared to provide a means of producing a permanently diabetic condition without recourse to surgical interference with the pancreas. To date, of six dogs treated with suitably large doses of extract only one had failed to become permanently diabetic. The remaining five had shown no sign of recovery from the diabetic condition, but their behaviour had differed in a number of respects from that of depancreatized dogs.

In explaining the differences between the behaviour of the permanently diabetic dogs and the depancreatized dogs, Dr Young said the diabetic condition of the former was due to a deficiency of insulin, but the islets could still secrete an amount of insulin which, if suitably administered to a completely depancreatized dog, would be sufficient to maintain life. In the depancreatized dog the diabetic condition was due to a deficiency of insulin which would lead to fatal inanition owing to the absence of pancreatic enzymes. The subnormal digestive powers of the depancreatized dog would not permit of the ingestion of sufficient non-carbohydrate food to cover the urinary loss of carbohydrates, but the diabetic dogs on which the experiments had been carried out were able to obtain sufficient calories by the ingestion of large amounts of non-carbohydrate food.

#### The Glycotropic Factor

In an attempt to purify the pituitary substance responsible for the effects obtained by Cope and Marks, Dr Young found that the active principle was present in preparations of the so-called lactogenic hormone—prolactin—though later investigations showed that the active substance was not identical with prolactin nor with the gonadotropic or thyrotropic hormones. There followed details of the investigations carried out with preparations of the glycotropic factor which were rich in prolactin but almost free from the thyrotropic and gonadotropic hormones. It was found that if two suitable injections of glycotropic-factor were given, one sixteen hours after the other, to a fasting intact rabbit, the hypoglycaemic action of 2 units of crystalline insulin, administered intravenously five hours after the first pituitary injection, was entirely abolished. Similar but less striking results could be demonstrated when the glycotropic factor was administered to hypophysectomized rabbits. The hyperglycaemic response to subcutaneously or intravenously administered adrenaline might be greatly increased under these conditions. All the responses could be demonstrated in rabbits in which the blood sugar level had not been significantly affected by the anterior pituitary injections alone. As a result of the findings of Dr Wesslow and Griffiths (*Lancet* 1936, 1, 991) it seemed possible that the plasma of a particular type of diabetic patient might contain an abnormal amount of glycotropic factor, which suggested that in some instances at least clinical diabetes might be of pituitary origin. If in some cases human diabetes was associated with excessive production of the pituitary glycotropic substance, the results of the administration to such cases of an antiserum to the glycotropic factor would be of interest. By the prolonged daily

administration to monkeys and rabbits of preparations of prolactin rich in glycotropic substance but containing no detectable thyrotropic or gonadotropic hormones it was possible to produce an antiserum highly active in neutralizing the action of prolactin in the pigeon crop gland but this serum exhibited no consistent antiglycotropic activity. The experiments did not prove that the glycotropic substance was incapable of evoking an antiserum and further investigation of the point seemed desirable, it only because such an antiserum might have some clinical value as well as physiological interest.

There was as yet no evidence that islet tissue to med under the influence of anterior pituitary extracts was capable of secreting insulin. It however one response of the dog's pancreas to diabetogenic extracts was a relatively slow functional proliferation of the islet tissue then the ability of a dog to become resistant to the diabetogenic action of a small daily dose of extract would be explained. It was clear that should it prove possible to prepare a pancreatotropic substance free from other undesirable anterior pituitary factors the investigation of the clinical uses of such a preparation might yield results of great interest.

#### Pancreatic and Pituitary Factors

Further investigations were necessary before any definite conclusion could be drawn concerning the identity of what might be called the diabetogenic complex of the anterior pituitary gland. Dr Young added that it was possible that in the normal animal the finely adjusted balance maintained between sugar production in the liver and sugar utilization in the extrahepatic tissues was controlled by the balanced antagonistic actions of insulin and the anterior lobe diabetogenic factor both acting peripherally on the muscles as well as on the central production of sugar in the liver. The case of the heart-beat might be analogous. The heart had the intrinsic property of beating rhythmically although the actual rate and type of beat were adjusted by the mutually antagonistic action of the sympathetic and parasympathetic nerve supplies. Similarly inherent processes of manufacture of sugar in the liver and utilization in the peripheral tissues probably existed these processes being intrinsic properties of the relevant tissues. The precise mutual adjustment of the rates of these two processes might be mediated by the endocrine system the antagonistic actions of insulin and the pituitary factors playing an important part in this adjustment. If that were so then freedom from diabetes was the result of a precise regulation of the relative effectiveness of the pancreatic and pituitary factors. If for any reason the regulation was faulty so that pituitary effects predominated then diabetes might result.

Whether the permanently diabetic condition resulting in dogs from anterior lobe treatment was a secondary phenomenon arising from islet lesions produced by the temporary diabetes or whether it was of primary significance and induced by a mechanism independent of that causing the temporary phase of the diabetic condition could not be decided at present. The first possibility was perhaps the more probable and it was correct then it might be found clinically that a short period of diabetes mellitus due to overaction of the pituitary gland might persist after the action of the hypophysis had returned to its normal level the persistence being due to pancreatic islet lesions.

It was clear that knowledge of the part played by the hypophysis in the aetiology of diabetes was still very elementary. The large number of published papers on the subject often mutually contradictory could be a source of embarrassment rather than an aid to future development. Perhaps few would disagree with the statement of Claude Bernard. It is that of which we are aware which is a great hindrance to our learning that which is yet unknown to us.

#### PSYCHOLOGICAL FACTORS IN ORGANIC DISEASE

At a meeting of the Medical Society of Indianapolis Psychology on May 12 with Dr H. C. SQUIRES in the chair a paper was read by Dr A. T. MACBETH WILSON on psychological factors in organic disease.

Drawing attention to the importance of nomenclature Dr Wilson defined organic disease not as a type but as a secondary stage of disease—a stage in which acute or chronic functional disturbances by either their severity or their chronicity had produced anatomical changes. Psychological factors were changes in the life of individuals related to their disease which were most easily described in the language of psychology. The bodily changes of emotion provided the link between psychological and physiological phenomena. Physiological disturbances of psychological origin might go on to organic disease which could in its turn produce further psychological and hence further bodily disturbance. The resulting clinical picture was apt to be complicated and was perhaps most easily understood by the use of a number of basic concepts.

#### Biological Tension

The first of these was what Dr Bacon had called the dispositions of organisms driven to satisfy certain needs. The second was the idea of traces—the fact that the mode in which the drives of the individual were satisfied was affected by experience and that some traces of a past event could influence current behaviour. The process by which the interaction of dispositions and traces produced a continuous satisfaction of needs despite changes in the environment was usually known as adaptation. Whenever adaptation became difficult it came into existence a state of biological tension which produced both psychological and physiological disturbances and the behaviour of the individual took on a character known as emotional which was most likely to mean more primitive. It apparently occurred as inevitably in the body as it did for example in the social behaviour of an individual who must necessarily make a certain journey and would if it was imperative successively use a car, a bicycle, walking and crawling.

It was sometimes a little difficult to understand the results of biological tension. To a large extent—a both clinical and experimental work seemed to indicate—physiological disturbances seemed to depend on the individual rather than on the specific nature of the physical or emotional stress which produced it. Similarly the degree or intensity of such physiological disturbances varied from one individual to another. Those who suffered from chronic tension were more likely to suffer stress to suffer disturbances when were more severe.

#### Body Speech

A concept of great value was that of the language of the body—the expression of emotion by alteration of physiological function. This concept was particularly important where adaptation had failed usually as a result of the situation known to psychologists as conflict. In this situation some drive of the individual became conflicted with self interests or self respect was banished from conscious expression and inhibited from being seen by body functions as were controlled by the central and the cerebral cortex. Such drives often continued to seek what satisfaction or expression was possible in spite of disturbances of those visceral functions which were controlled in this way. The situation might also be described as one of unrecognized biological tension. An important concept of which there was ample experimental and clinical corroboration. Asked about the relation of an individual might make to contradictory replies—such

in words and one in the language of the body. The second might be the correct reply, as in some instances of blushing.

What might be described as the idiom of body speech varied from one individual to another. The importance of understanding the idiom lay in the light it might throw on the origin of conflict—that is, of the need to speak in two languages. Although not of immediate therapeutic interest this was important in the prevention of disease, since to translate the patient's body speech into words, to interpret his physiological symptom was often of little value and might do harm. The aim of treatment in such circumstances was to lead patients to make their own interpretations.

### Gastric and Cardiac Manifestations

Previously reported investigations on peptic ulcer had shown that 84 per cent of 205 patients had passed through some disturbing event in their lives just before their symptoms began. In fifty-two cases of recurrent ulcer, in which there existed radiographic evidence of the return of a previously healed ulcer, forty-two of the patients had suffered gross disturbances in their lives before the recurrence, although they had not necessarily noticed the obvious connexion in time between external and internal events. To be in a position to convince first oneself and then the patient of this connexion removed much of the mystery from peptic ulcer and made treatment and prevention of recurrences more easy. Prevention of ulcer, a disease which caused 4,600 deaths in 1936, might be partly accomplished by adequate explanation and treatment of the dyspepsia, which so often existed for years before an ulcer appeared.

Work on cardiac pain by Bourne, Scott, and Wittkower had shown that there were two available theories of recurrent attacks of pain related to ischaemic disease of the heart—some change in the local conditions, or a visomotor change the result of a biological tension which might be as unrecognized in recurrent as it was obvious in single attacks. The psychological investigation of patients lent much weight to the second theory which had the additional advantage of explaining the differences in what was called sensitivity to pain. These cases of ischaemic disease of the heart showed clearly that psychological disturbances might arise from organic disease and produce secondary physiological disturbances affecting the symptomatology of the condition. That patients should express as they often did a feeling of relief after a severe haematemesis seemed to be a related phenomenon—a psychological effect of severe physiological disturbance strongly resembling the behaviour of the soldier with a blighty.

### CUTANEOUS AND CONJUNCTIVAL DIPHtheria

A meeting of the Section of Medicine of the Royal Academy of Medicine in Ireland was held on April 22, with the president Dr E. T. FREEMAN in the chair.

Dr H. R. ROGERS described eleven cases of cutaneous and conjunctival diphtheria seen in the Cork Street Hospital during the last four months of 1937. Seven of the eleven cases also had non-diphtheritic conditions: two had concurrent scarlet fever, three erysipelas and two measles. In two cases only was the cutaneous or conjunctival diphtheritic lesion the sole infection present. Two of the patients died and in each case the cause of death was an associated streptococcal condition. In the five cases of cutaneous diphtheria the association of impetigo of the face or limbs with a diphtheritic or erysipelous condition led to the swabbing of the skin lesions. The conjunctival diphtheria was bilateral in five of the six cases of this condition and six of the seven cases showing cutaneous lesions had diphtheria of the throat or nose. These rare forms of diphtheria were not

associated with much toxæmia, and cardiovascular changes of diphtheritic origin were not observed. All the cases occurred in children. The diphtheria bacilli isolated were either of the gravis or intermediate type.

In the discussion which followed the president of the Academy, Dr A. R. PARSONS, Dr T. A. BOUCHIER HAYES, Dr L. B. SOMERVILLE, Dr C. MURPHY, Dr J. C. FLOOD and Dr ALAN THOMPSON took part. Dr R. A. Q. O'MEARA then read a paper on the use and abuse of sulphanilamide and related substances. A long and interesting debate followed, those taking part including Dr G. C. DOCKRAY, Dr C. J. McSWEENEY, and Dr V. M. SYNGE.

## Local News

### SCOTLAND

#### Finance of Scottish Universities

The Committee of Inquiry appointed by the Secretary of State for Scotland in April, 1937, has recommended the payment of grants out of the Education (Scotland) Fund to the four Scottish universities as follows: Glasgow £21,000, Edinburgh £13,000, St Andrews £5,000, and Aberdeen £4,000. These sums have been chiefly determined by the amounts necessary to enable the universities to balance their budgets for the present year. In the case of Glasgow this amounted to £12,000, and of Edinburgh to £4,000. Before the committee was set up it was pointed out by the Scottish universities that the number of students resorting to them was notably higher in proportion to the population than was the case in England and Wales. Indeed the Scottish universities made provision for over 20 per cent of the total number of students in Great Britain. Edinburgh and Glasgow had been able to preserve their solvency only by encroaching upon capital or by borrowing. Edinburgh had just managed to make ends meet in 1936-7, but a deficit of £4,000 was expected on the present year, while Glasgow had been under-financed for several years. The total Treasury grant annually distributed to the universities of Great Britain amounts to £2,025,600 and on the standard formula of receiving 11/80ths of what accrues to England and Wales the Scottish universities would be entitled to about £220,000, while in point of fact the Scottish universities are getting £346,750. In England contributions amounting to 8.7 per cent of the income of the universities are payable by local authorities direct to the universities in their areas, but in Scotland the income derived from local sources amounts to only 4.2 per cent of their income. The Scottish universities, it is pointed out by the committee, are well off in the matter of bursary and scholarship endowments administered by the universities, which have a revenue of nearly £70,000 a year, in addition to trust funds controlled by non-university bodies. The committee's report is published by H. M. Stationery Office, 120, George Street, Edinburgh, price 6d.

#### A Nutrition Inquiry

The inquiry into the connexion between economic and social factors and physical welfare conducted under the direction of Sir John Orr of the Rowett Research Institute, Aberdeen, to which reference was made in these columns on March 12 (p. 586) is further described in the annual report of the Carnegie United Kingdom Trust. The work which is proceeding includes an economic and dietary survey of 1,000 representative working class families, with a clinical examination of the children of the families surveyed, also a demonstration of the effect on health and physique produced by bringing the diet

of some 200 families to a higher level. The staff consists of a dietary survey team of nine trained women, a clinical team of two qualified medical practitioners with two assistants and four recorders of statistics. The report also gives details of the survey of Scottish village life completed during the early part of last year which was carried out by questionnaires addressed to the head teachers of rural schools in some 2000 Scottish villages. It was found that approximately half the villages in Scotland did not possess adequate hill accommodation which is considered to be essential to social organization and the Trust will assist some fifty villages to erect halls.

## ENGLAND AND WALES

### National Fitness Council Medical Committee

The National Fitness Council for England and Wales has set up a Medical Committee with the following terms of reference. To take such action as may be found desirable in order to enlist the co-operation of the medical profession in promoting the policy of the Council and to consider and report on the medical aspect of the Council's work. The membership of the committee as at present constituted is as follows: Chairman Lord Dawson of Penn M.D. Vice Chairman Sir Kave Le Fleming M.D. Dr Adolphe Abrahams Dr Anna B. Broman Dr George Chesney Dr G. E. Friend Major A. H. A. Gurn Dr J. Alison Glover Dr L. Haden Guss MP Dr L. P. Lockhart Captain J. G. Paterson Dr J. R. Rees and Miss P. Spafford. The first meeting of the committee will be held on June 2. The address of the National Fitness Council for England and Wales is 1 Queen Anne's Gate Buildings Dartmouth Street, SW1 (Telephone: Whitchall 9060).

### National College of Physical Training

The Board of Education and the National Fitness Council after considering a large number of possible sites have chosen one at Merstham in Surrey for the National College of Physical Training which is to be erected under the Physical Training and Recreation Act for the purpose of training teachers and leaders. It consists of 220 acres on the Merstham Manor Estate in a very attractive part of the North Downs. Part of the site forms an almost level plateau nearly 600 feet above sea level, and has very good views of the surrounding country. There are several areas of woodland and groups of trees and Alderstead Heath a public open space is adjacent. The land is protected on all sides not only by natural features but also by town planning schemes while close by are areas acquired in connection with the Green Belt. The site comprises three portions: the main portion of 130 acres including the plateau will probably be used for the college buildings and training grounds, a detached portion of nearly forty acres is admirably suited for playing fields being level and well screened by belts of trees while adjoining fields of about fifty acres are available to meet future needs. The soil is very suitable for grass and there should be little difficulty in providing lawns and playing fields on any part of the site. The college when built will be a national centre for the study and practice of physical training in all its aspects and will supply teachers of physical training for elementary and secondary schools together with organizers and leaders for the new fitness movement.

### The Cancer Campaign in Yorkshire

The Earl of Harewood presiding at the annual meeting of the Yorkshire Council of the British Empire Cancer Campaign at the Leeds Medical School announced that income now very nearly met expenditure. Professor R. D. Passy, head of the cancer research laboratory in the Algernon Firth Pathological Institute of Leeds

University presented a report with comments on the cancer situation in Yorkshire under his direction. He spoke in particular of the influence of prolonged inter-uterine infection on the development of cancer of the cervix and of the bladder and human cancer. He said that Walter H. Norris and his wife in Holland had lately examined the family histories of patients suffering from cancer and claimed to have shown that in both countries the incidence of cancer in certain sites in the body though not in all sites was higher in some families than in the population at large. To ascertain if the same was true in this country Dr Joyce Rhodes had begun an investigation of similar lines employing material obtained from the General Infirmary at Leeds and the Bradford Cancer Committee. The annual report of the work of the Yorkshire Council was presented by Sir Harold Macintosh. He said that it was the need for the campaign was great when the inaugural meeting was held in 1925 it was more so to-day. The work of the Propaganda Committee had done much in recent years to create a more rational and sensible attitude of mind towards cancer. Sir Edward Mellanby also addressed the meeting.

### Health Congress at Blackpool

The annual congress arranged by the Royal Institute of Public Health and Hygiene will be held next week at Blackpool from Tuesday May 31 to Saturday June 4. At the inaugural meeting the mayor will offer an official welcome to delegates and Lord Cozens Hard will give his presidential address followed by a civic reception and dance. The work of the congress is divided into five sections—(1) State medicine and industrial hygiene, (2) women and children and the public health, (3) tuberculosis and physical training—all of them meeting in the Technical College, Palatine Road. The local hospital, a crèche, welfare centre and other social services will be open for inspection by members bearing the congress badge and visits have been arranged to Preston Lytham St. Anne's Royal School and the Fylde Water Board's new reservoir. There will also be an exhibition of a film on physical fitness as promoted in Lancashire schools and a demonstration of physical exercises by members of the Lancashire Keep Fit movement. For further particulars can be had from the Secretary Royal Institute of Public Health and Hygiene 28 Portland Place London W.1.

## IRELAND

### Radiologists Meet in Belfast

The four biennial annual meeting of the British Association of Radiologists was held in Belfast on May 13 and 14. The scientific sessions taking place at the Whitla Medical Institute by permission of the Ulster Medical Society. At the opening session on Friday morning Dr R. Maitland Beath who was inducted as president by his predecessor in office Professor J. Woodcock Morrison gave an address on the history, activities and aims of the Association. This was followed later in the morning by an address from the guest of honour Dr P. Fiernberg Moller of Copenhagen on chronic fluorine poisoning as seen from a radiological standpoint. The afternoon was devoted to three papers on radiodiagnosis. A Paper on Radiography of the Fourth Ventricle by Dr T. G. Hart Hardman Dublin. Brocas Abscess and its Differential Diagnosis by Dr J. F. Brailston Birmingham and Syphilitic Aortitis and Aneurysm of the Aorta by Dr. Peter Kerley London. On the same day a visit was paid to the Royal Victoria Hospital and members were given an opportunity of inspecting the General Hospital, the Royal Maternity Hospital and the new open Magdalen Clinic. The annual dinner was held in the evening at Thompson's

Restaurant, the guests including Sir Robert Johnstone (President of the B M A), Dr Moller, the Vice-Chancellor of the University Mr C G Lowry (Professor of Gynaecology Queen's University), Mr Henry Hanna (Chairman of Medical Staff Royal Victoria Hospital), Mr Howard Stevenson (Senior Surgeon, Royal Victoria Hospital), and Dr J C Rankin (Physician in charge of Electrical Department Royal Victoria Hospital). The subject at the Saturday morning session was radiotherapy, two papers being presented by Dr S Cochrane Shanks, London, on "Four Area Methods of X-Ray Treatment of Tinea Tonsurans," and Drs J Ralston Paterson and Margaret Tod, Manchester on "The Radium Treatment of Angiomata in Children."

### Nutrition in Denmark During the War

SIR—May I correct any misunderstandings which may have arisen from Dr Alfred C Jordan's reference to the rationing of foodstuffs in Denmark in 1918 (*Journal* April 30, p 973). Rationing became necessary in this year

but his "dictatorial powers" were simply part of a myth which ought to be exploded. The rationing was forced on us by the circumstances then existing, and the director responsible for it was Professor H Mollgaard, who was supported by Dr Hindhede and several other people.

The directors of this scheme were surprised to find that the results of this rationing showed the importance of animal nutrition, thus supporting the modern views of McCollum, Mellanby, and Orr. The supposed "Spartan diet" of 1918 has for too long been quoted in support of the vegetarian faddism of Hindhede. It is an established fact that the Danish people never lived better than in 1918, when they had genuine home-made—mostly animal—food without any imported substitute foodstuffs. It was especially the poor people who benefited because of the equal distribution of butter and milk (instead of margarine and skim milk). It is especially dangerous for the nutrition of poor people if this great and important experiment with the dietary of three million people is misquoted and wrongly explained, as it has been for twenty years.

For full comprehension of the accompanying chart, which has never before appeared in an English journal, it is necessary to remember that the decreased mortality is counted from October 1, 1937, to October 1, 1938, the

Nutrition and Mortality in Denmark, 1901 to 1935

because margarine—which provides too great a proportion (15 to 20 per cent) of the calories in the Danish dietary—could not be imported, consequently the consumption of this substitute foodstuff was reduced almost to zero in the autumn of 1917. It became necessary to restrict the export of butter and a weekly ration of 250 grammes was allowed for each person. All small children were allowed 1 litre of whole milk (against Dr Hindhede's views) and the consumption of meat and fish increased considerably (this also was against Dr Hindhede's views). Free trade was possible in meat and fish, but potatoes were scarce, bread restricted and the imports of fruit diminished. To make up the loss of calories previously provided by margarine it was necessary to eat more milk and meat. The only part of the usual conception of this rationing which is true is that the bread was whole rye and whole-wheat because the import of foreign meal was stopped. Dr Hindhede certainly gave advice regarding the bread,

full mortality of the whole year 1918 rising to 13 per thousand because of the influenza epidemic which began in Denmark in October, 1918—I am, etc.,

Copenhagen

JOHANNES CHRISTIANSEN

### Problems of Thyrotoxicosis

SIR—The figures given in Mr Peter McEwan's most interesting paper (*Journal* May 14, p 1037) prompt the suggestion that the variations in the incidence of thyrotoxicosis throughout England and Wales have to a large extent a racial basis.

Mr McEwan's map on page 1039 bears an almost startling resemblance to those ethnographical maps that show stature, the amount of brunetness or the like. Wales shows a much higher death rate from thyrotoxicosis in 1936 than England, and Cornwall is fourth amongst the English counties. Much more striking evidence, however,

is provided by an area to the north of London Ripley (*The Races of Europe* 1899) states on pages 22-3

One detail of our map confirms us in this opinion that a primitive dark population in these islands now mainly of Celtic speech has been overlaid by a lighter one. Notice the strongly marked island of brunettes just north of London. Two counties Hertfordshire and Buckinghamshire are a dark as Wales and others north of them are nearly as unique. An investigation goes to show that this brunette outcrop is a reality. It is entirely severed from the main centre of dark eyes and hair in the west by an intermediate zone as light as Sussex Essex or Hampshire. Our stature map on page 227 makes the people in this vicinity very much taller than those about. This betokens a British lineage. In a later chapter considering purely social phenomena we shall show that peculiarities in suicide land tenure habits of the people and other details of the counties are likewise the concomitants of this same racial isolation. The fact is all the more striking because the district lies so close to the largest city of Europe. Again on page 221. Most remarkable of all is the little area just north of London comprising the counties of Hertfordshire Bedford and Huntingdon. This district we were at great pains to emphasize in our chapter upon the British Isles as a region where the physical characteristics of the pre-Teutonic invaders of the island were still represented in comparative purity.

This racial island may be taken to lie within the counties of Hertford Buckingham Bedford Northampton Huntingdon, and Cambridge. Of these six counties no fewer than three appear amongst the six English counties with the highest death rate from thyrotoxicosis—the other three all show incidences above the average. If it is a coincidence it is a most remarkable one that Mr McEwan's map should so faithfully reproduce the most curious feature in the ethnographical maps of this country.

I have made one further comparison. Beddoe (*The Races of Britain* 1887) gives a map showing an index of nigrescence which was the measure he adopted for assessing the brunetness of the population. Not all the counties are shown separately but adding together Mr McEwan's figures where necessary 33 comparisons can be made. The correlation coefficient between the index of nigrescence in 1885 and the death rate from thyrotoxicosis in 1936 is without weighting no less than 0.42 a value that is amply significant with 33 pairs of observations.

It would be interesting to see whether further observations covering other periods and other areas—for example France—confirmed the hypothesis that thyrotoxicosis exhibits a racial incidence. It is difficult to think of any other hypothesis that would account for the geographical variations that have been so clearly displayed by Mr McEwan—I am etc.

J. A. FRASER ROBERTS

Burden Mental Research Trust  
Stoke Park Colony, Bristol  
May 19

SIR—Mr Peter McEwan in his illuminating article on thyrotoxicosis in the *Journal* of May 14 points out that deaths from this disorder are highest in the counties of Merioneth, Cardigan Westmorland Huntingdon and Caernarvon. There are features in Merioneth and Caernarvon which bear on this problem—namely the migration of the young and strong and the low standard of living—both consequent on the depression in the slate industry.

The slate industry is the most important single industry in the two counties but unemployment among the workers in the Caernarvon area during the past eight years has averaged more than 31 per cent. Further the average wage of those in employment is far lower than that of workers in any other extractive industry—namely 45s 1d

per week. The next lowest industry is stone quarrying 31s 3d while the average for 230 industries in Great Britain for the same period was 64s 6d. This accounts for the steady migration of the young and strong which is shown in the census returns. Here we find that if the proportion of persons between 20 and 24 years of age in Great Britain is taken as 100—the proportion in the Gwynedd (a quarrying and agricultural district) is only 77 whereas the proportion of workers in the 65-69 age-quinquennium is 130 compared with 100 for the whole of Britain. Further in the pre-war years the average wage in the slate industry (and with it the standard of living) was appallingly low—24s 11d per week compared with a bricklayer's 40s 7d.

We therefore have a population chronically undernourished from which the young and strong elements are continually being removed and this seems to me to be the cause of the high incidence of thyrotoxicosis—autumn states deficient vitamin and relatively low resistance to infection remain. It must be realized that these facts apply only to the quarrying industry, the standard of health in the immediately neighbouring agricultural and seaside districts is high.

I am indebted for the foregoing figures to Mr Dylan Pritchard M.A. F.S.S. whose report was prepared for the recent inquiry into the incidence of tuberculosis in Wales—I am etc.

GRIFFITH EVANS  
D.M. FRCS.

Caernarvon May 20

SIR—I should like to thank Mr Cecil A. Joll for his kind reference to my article on this subject (*Journal* May 21 p. 1125) and for emphasizing his views as to the danger of iodine medication in thyrotoxicosis. Mr Joll also refers in connexion with one of the cases I quoted to that most controversial problem—thyrotoxicosis in the absence of an enlarged thyroid gland. He delicately points out that the photographs prove nothing as regards the size of the gland but I had meant those to illustrate the point not to prove it. I considered that the clinical facts established the diagnosis in this case. The report of the microscopic section however was oedema and some areas of fibrosis and degeneration. Colloid storage was diminished and some of the vessels contained finely granular material. Epithelial hyperplasia was not present. My intention was to direct attention to this group of difficult cases in which hyperthyroid symptoms are present but in which it is difficult to differentiate the gland from the normal and I am glad to have elicited Mr Joll's method of dealing with this very real difficulty—I am etc.

Bradford May 23

PETER MCEWAN

### Diethyl Ether Anaesthesia

SIR—The letters in the *Journal* on this subject from Dr E. B. Grogono (May 14 p. 1068) and Dr John Elam (May 21 p. 1127) should prove valuable in bringing this serviceable anaesthetic into more general use. Dr Elam's letter ends with the hope that some of our expert anaesthetists will carry out further work on this valuable agent. This excellent proposal further suggests that Dr Elam and possibly many others are unaware of the history of the drug and of the manner in which it was introduced into this country.

It had long been known that diethyl ether possessed anaesthetic properties but difficulties in manufacture and stabilization prevented its general use. Messrs. Mure and Co. of Rahway, New Jersey, after prolonged research were able to overcome these difficulties and produce an

efficient and relatively stable form of divinyl ether which they introduced under the name of vinethene, later changed to vinesthene. Numerous clinical trials were made for them in America, and the exact action of the drug was exhaustively experimentally examined by Dr Hans Mollitor, their distinguished pharmacologist. Before, however, allowing any of the preparation to be sold in England, Messrs Merck asked the Anaesthetics Committee of the Medical Research Council and the Royal Society of Medicine to conduct a clinical investigation of its properties. Dr Mollitor and Dr Randolph Major (their research chemist) attended a meeting of the committee in London and placed all their information at our disposal. They also arranged to have forwarded to us adequate supplies of the product.

Sir Francis Shipway, Dr Langton Hewer, and myself all made careful notes of its action in large numbers of cases and some four or five other anaesthetists also gave their assistance with more limited numbers. The results of all these observations were then pooled and a paper on vinethene was published, on behalf of the Committee, by Sir Francis Shipway in both the *British Medical Journal* (p. 70) and the *Lancet* (p. 82) on January 12, 1935. It will be remembered that a similar procedure was employed in the case of both avertin and evipan. Since that time Messrs Merck have appointed Messrs May & Baker as their agents in this country and the latter firm now import vinesthene, and I understand partly manufacture it at Dagenham, and are the sole agents for marketing it here.

The merits of vinesthene have been so well described in the letters mentioned above that I need add nothing. However, while on the subject I would like to mention one or two points that might lead to disappointment if not realized beforehand. Dr Grogono refers to the price (about 3s per ounce), which makes administration by open methods rather costly. This is unfortunate, as I have found it far the best method of administration for children for whom it is a particularly suitable agent owing to the small amount of mucous secretion. Although much more potent than ether it is also far more volatile, and so considerable quantities have to be used on an open mask. This great volatility causes another trouble. Although the bottles in which Messrs May & Baker pack vinesthene are most elaborately stoppered and sealed I have sometimes found one nearly or quite empty after being stored in a cool cellar for some little time. Again though relatively stable while in the sealed bottles (it is packed in an atmosphere of nitrogen), it quickly depreciates when once opened and should not be used after the lapse of a few hours.

Vinesthene has a rather unpleasant odour, suggestive of garlic but this odour is extraordinarily evanescent. It disappears from the air of the operating theatre and from the patient's *breath* in a remarkably short time. A ward sister to some of whose patients I was accustomed to give vinesthene on the mornings preceding visiting afternoons was loud in its praises. She told me that her ward was free from the smell of anaesthetics when her visitors arrived which was far from being the case when ordinary ether was used.

Vinesthene should not be given when there is any suspicion of defective liver function. Further even than this Dr Mollitor does not recommend its use, as the major agent in prolonged operations. As an adjuvant this warning would hardly apply. As to potency, it must be remembered that vinesthene lies somewhere between ether and chloroform and probably rather nearer the latter. So the possibility of overdose must not be overlooked.

In my view the best method of administration is with a gas-and-oxygen apparatus, such as a Boyle's, when it will be found that passing the gases over the surface of the vinesthene will usually give adequate relaxation without bubbling them through the liquid.

It is most distasteful to me to criticize any opinion of such an authority as Dr Elam, but I feel compelled to warn strongly anyone less experienced than he is against using vinesthene in a Clover's inhaler. We all know that the surest way of killing a patient with an anaesthetic is inadvertently to place chloroform instead of ether into a Clover. Vinesthene is nearly as potent as chloroform. *Verb sap.* The only other instance in which I have heard of vinesthene being used in a Clover's inhaler happened by inadvertence while we had the substance under test. It proved rapidly fatal—I am, etc.,

London, W.1, May 23

### Perforation in Typhoid Fever

SIR,—In Sir William Willcox's account of certain cases in the Croydon typhoid epidemic published in the *Journal* of May 21 there occurs one paragraph upon which I am surprised that he did not make some comment—namely, the paragraph about perforation on page 1086. "*Perforation of the ileum* occurred in one case. This was recognized early, and all liquids by mouth were withheld for three days, recovery followed without operation." As there was only one case of perforation this paragraph presumably refers to Case 1 recorded on page 1090 where it is stated that the patient died twenty-five days after perforation, apparently from the effects of toxæmia due to the *B. typhosus* and not to any sequel of the perforation. In this account the fact of perforation is referred to as briefly as if it were a triviality instead of the most dreaded and deadly of the complications of typhoid.

Many years ago in a discussion on perforation in typhoid at one of the medical societies of London I was somewhat sharply taken to task by the late Sir John Bland-Sutton for venturing to suggest that a patient might recover from perforation without operation, because, he said, you cannot be certain that perforation has occurred unless you have the evidence of either a necropsy or an exploratory laparotomy. Sir John was, I now think, right, for, though I have seen two cases in which I believed perforation with recovery had taken place without operation, I am convinced that I should have had great difficulty in proving in a court of law that my diagnosis had been absolutely correct. It is quite certain that symptoms justifying operative intervention may occur and yet an exploratory laparotomy will show that perforation has not taken place, there may, indeed, be no macroscopical morbid condition whatsoever.

Further, the paragraph I have quoted above would I think, lead any practitioner who has had no, or little, experience of enteric fever to conclude that the best way to treat perforation is to withhold all liquids by the mouth and trust to nature. Sir William does not deal with perforation in his paragraphs on treatment. One asks why, if perforation was diagnosed early in this case, recourse was not had to operation. The only contra-indication to operation is a moribund state of the patient and if this patient was the one referred to in Case 1 possibly that was the reason. Perforation of an abdominal viscus in typhoid if not operated upon is almost invariably fatal—I am, etc.,

Hemlingford Abbots, Hunts, May 22 E. W. GOODALL

## The New Divorce Law

SIR—This law enacted to relieve the hardship and cruelty unintentionally inflicted upon an innocent family must be in the public interest and in view of the statement made by Mr Justice Humphreys as President of the Medico Legal Society on April 28 (and reported in the *Journal* of May 7) I hope I may approach you further. The occasion was of a very full and instructive paper read by Mr William Latcy dealing with the question of incurability of insanity as a ground for divorce under Sec. 2 (d). The judge stated that this question will not be left to the medical witness to decide but that the judge himself would as in every other case come to his conclusion of fact upon the evidence. A remark was recently made to me by a High Court Judge that he himself was much perturbed as to the meaning of incurability. How could I be satisfied that a case was incurable? The paper referred to helped to clear the issue and it is hoped will soon be published.

As a consequence of the Act the hardship and pitiless neglect inflicted upon a family of young children dependent on a parent suffering from incurable insanity will be mitigated in spite of some moral prejudices presented and it may be helpful to state that there are many safeguards against the improper detention of a patient certified to be insane which imply that any patient detained for over five years is probably incurably insane.

The Act states that a petition for divorce may be presented to the High Court by the husband or wife on the ground that the respondent is incurably of unsound mind and has been continuously under care and treatment for a period of at least five years previously and preceding the presentation of the petition.

It would appear to be impossible to detain a recovered case after the period fixed by the Act—namely five years—and only those who were deemed incurable would remain and for the following reasons: (1) It is required by law for the protection of the patient that within one day of the reception of a patient under care a copy of all the admission papers (certificates orders etc.) must be forwarded to the Board of Control (Lunacy Commissioners). (2) The patient must be examined fully both physically and mentally by the doctor within seven days of admission and the result as a statement to this effect must by law be sent to the Board of Control who may make further inquiries and demand a further report if they think fit. (3) Before one month has expired after admission another medical statement justifying detention must be made and sent to the Board of Control. (4) Before the expiration of a year if the patient is still detained another medical statement must be made and sent to the Board of Control and (5) yet others at the expiration of the second fourth and seventh years and after that (6) a further report must be made every five years. These reports are to the effect that the patient is still of unsound mind and a proper person to be kept under care and treatment. As additional safeguards one or two members of the Board of Control visit all public mental hospitals once every calendar year and a private interview is granted to any patient desiring one when any complaint regarding detention or treatment can be made. The private licensed houses in the London area are visited officially six times a year and two visits are made by them to private asylums outside this area as well as four visits by local Justices of the Peace. In addition a patient it well enough may be granted leave of absence for a period of forty eight hours. All voluntary patients may leave at any time on giving three days notice. Further all letters written by patients to the petitioner the Board of Control and to others (specified) must be forwarded unopened. It thus appears there is a great unlikelihood of any sane patient being detained improperly and I quote these facts as a reassurance to show

that no certified person—unless demented and incurable—is likely to be detained in an asylum.

Recovery after five years is not impossible though unlikely and improbable. In 1000 cases I have known improvement sufficiently definite for the patient to be discharged in only four cases after twenty years detention but there is always the possibility of a relapse. My personal experience is that less than 5 per cent of all cases of insanity recovered after they had been detained over five years. The late Sir George Savage a leading authority on mental diseases supported me and held that even after an acute and short attack of insanity although recovery had taken place a permanent scar was left on the brain. There has been much uncertainty on the part of medical officers in charge of insane patients (1) whether they should be compelled to give the information about incurability of a husband or wife. A medical officer has no desire to obstruct the Act and render the law of the land ineffective and inoperative. If he refuses the information does he stultify the law and render himself liable to punishment? Also can the Court demand the information? The number of cases where a petition being sought for is likely to be a serious one is already into four figures but I have been informed there is much hesitation and demur. (2) Is the doctor giving the information protected if he describes a patient as incurable and this patient should subsequently be cured? (3) If the doctor in charge declines to give the information and an outside specialist is brought in will the local authority detract the expenses in the case of a 'stale' patient? (4) Will the local authority in the case of patients from a public institution detract the costs of an action at law arising out of the proceedings? (5) Is it a betrayal of professional secrecy to certify incurability? Several of these points have been considered by the British Medical Association and also by a committee of the Royal Medico-Psychological Association but other points must necessarily arise and it will be a satisfaction if help can be given to those desirous of doing their duty under the new Divorce Act to individual patients and to their friends and to the State. Already complaints are being made and requests urged for an amendment in Parliament to omit this clause in the Act as to incurability—I am etc.

London W 8 May 21

ROBERT ARYSTRO G-JO ES

## Pneumonia, Subphrenic Abscess, Duodenal Fistula

SIR—In the most interesting case described by Sir Arthur Hall Mr Graham S Simpson and Dr J L A Grout in the *Journal* of May 14 (p. 1043) it is difficult to imagine the pus from an empyema going through the diaphragm to form a subphrenic abscess and then this abscess bursting into the duodenum. Is not the reverse direction more likely? I have seen cases in which the duodenum has been perforated without vomiting or previous symptoms of duodenal ulcer causing rupture. Friction between the liver and the diaphragm which is mistaken for pleurisy. Following this a subdiaphragmatic abscess develops which gives rise to dullness at the right base due to collapse of the lung by pressure and this is thought to be pneumonia by the medical attendant. But on percussion in front of the chest instead of dullness there is a tympanic area over which a dullness can be obtained with coins owing to the abscess containing gas. Such an abscess if allowed to persist does often perforate the diaphragm and cause empyema.

and may also cut into the lung so that sputum may be coughed up. Most of the cases of subdiaphragmatic abscess that I have seen have been referred to me because of pneumonia—I am, etc.

Hove, May 18. WALTER BROADBENT, M.D., F.R.C.P.

### Psoriasis

SIR—I have read with interest the paper on psoriasis by Dr J. T. Ingram in the *Journal* of April 23 (p. 881). Dr Ingram gives the impression that a hot sunny climate is an infallible treatment for psoriasis. He states that if the patient can be transferred to a hot and sunny climate the psoriasis spontaneously disappears. Again, that it is well known that in a cold, stormy and sunny climate the psoriasis will disappear and will not reappear so long as the patient remains in that climate. It is obviously fatuous, therefore, to suggest that treatment is useless. Finally, he says that ultra-violet light therapy is undoubtedly the next best thing to being able to live in those climates where psoriasis does not exist.

The Northern Sudan fulfils all requirements as to a very warm and sunny climate. During my service therein my work has brought me very little into contact with psoriatic patients, and I can form no impression as to the prevalence of psoriasis among the white population. I have, however, in the last six years in the Sudan met with two white subjects of psoriasis.

A man who has been over ten years in the Sudan. To my knowledge he has rarely been free from typical psoriatic patches for the last six years. Before coming to live in the Sudan the only manifestation of the state which he had noticed was an affection of the nails which now show characteristic pitting. A diagnosis of psoriasis had not been made.

A man whom I was asked to see in consultation. He was suffering from what at first sight appeared to be a generalized seborrhoeic dermatitis. The presence of characteristic demarcated lesions in the scalp and over the knees and interolateral aspect of one leg made a diagnosis of psoriasis clear. He had been resident in the Sudan for at least nine months.

About nine years ago in England I came across a case of longstanding psoriasis in a middle-aged woman who had lived for many years in Cape Town. The disease had first appeared there. Her condition failed to improve with ultra-violet light treatment.

Psoriasis is certainly not non-existent among natives of warm and sunny climates. In 1931 I saw Dr P. H. Manson-Bahr demonstrate a case in a Lascr sutor. It is my impression that psoriasis is not uncommon in natives of the Sudan. During some three years in which I was seeing out patients at the Khartoum Civil Hospital I was able to show a number of typical cases to students of the Kitchener School of Medicine. Some of these cases, submitted to biopsy, presented a consistent histological picture. During the current year I have seen two cases of the condition in the White Nile Province. Both cases had been diagnosed by a Sudanese medical officer of the Sudan Medical Service. It is my experience that graduates of the Kitchener School of Medicine are familiar with, and have little difficulty in recognizing, psoriasis—I am, etc.,

El Dugim, Sudan, May 13

HENRY RICHARDS

SIR—In the article on "Some Problems in Psoriasis" by Dr John T. Ingram in the *Journal* of April 23 two rather dogmatic assertions seem to me, as a general practitioner who has been troubled with this scourge since puberty, to require a little modification. The first is 'We all know that if the patient can be transferred to a hot and sunny climate the psoriasis spontaneously dis-

appear.' This may be true in the majority of cases but in many cases the psoriasis has been in India and Mesopotamia for many years and would very probably persist if the complaint were not once and for all at the end of this period and in a hot climate in the state. I am sure that even if the patient of a worthy person could afford to take such a holiday he would be far from cured and psoriasis in a climate would be decidedly cured.

Another point which vexes me is the detail which we are given in the article of the complaint and its treatment afforded by the patient. Pregnancy and not a course of treatment of several weeks of active breaks of psoriasis. This may be a bit hardly helpful to a doctor and the following case I saw was under my care. A woman who had been affected with the scourge from the age of puberty up to her marriage about ten years later found of a sudden that of conceiving and becoming a mother the psoriasis mysteriously disappeared without a further effort to labour or even to consider treatment and the cure was completely clear. When we first discuss a problem that the shock can either cure or combine it appears then it would seem that our knowledge of it is very meagre and the cure is a fact of God.

I read the article not in an cynical spirit for I enjoyed and was helped by it considerably. The two points I have raised may call for an explanation but a satisfactory one I am at a loss to give—I am, etc.

Worcester, May 17

J. G. BENNETT

### Sterilization of Syringes

SIR—In the *Journal* of May 13 (p. 1070) Dr J. Sandison Crabbe describes the method of sterilizing hypodermic syringes with olive oil heated till a crumb of bread in it turns brown and mentions that he has used it for over thirty years. It may be of interest to note that this method was in use at the Pasteur Institute in Paris as long as 1890. In the early spring of that year I attended Dr Roux's course of practical bacteriology and saw this method used for sterilizing the syringes which were employed in the treatment introduced by Pasteur, of those who had been bitten by animals suffering from rabies—I am, etc.,

Manchester, May 21

GEORGE R. MURRAY

SIR—May I suggest that pure carbolic acid may be very usefully employed in quickly and satisfactorily sterilizing hypodermic syringes. The needle is immersed in the carbolic and the fluid is drawn up into the barrel, thereby sterilizing the interior of the syringe as well. After about a minute's immersion the carbolic is removed by boiled sterile water and the syringe is ready for use. The carbolic acid can be easily carried in the practitioner's bag if stored in a well-stoppered bottle enclosed in a wooden case. In addition a small measuring glass, into which the antiseptic is poured for the purpose of the immersion, may be added to the equipment. The same method can be applied to the sterilization of forceps, scissors, etc., in the treatment of minor injuries which come to the surgery. One or two fairly wide-mouthed glass jars are kept ready filled with liquid carbolic acid, into which the essential parts of the instruments (those which touch the wound) may be immersed. They are quickly sterilized, and are then removed into the antiseptic lotion which is used for washing and cleansing the wound. A couple of sugar-tong forceps act admirably as fingers for handling the cotton wool and dressings,

and the wound need not be touched by the surgeon's hands. I have found that this procedure yields good results—I am, etc.,

Rhyl May 16

J JONES

SIR—I have followed with interest the many methods of sterilizing hypodermic syringes described in the *Journal* in the past few weeks. May I mention another method that does not appear to be generally known?

I carry in my bag a two ounce bottle of chloroform. Having assembled my Record syringe I dip the needle into the bottle and suck some chloroform into the syringe. The syringe is then held point upwards and shaken to make sure that the whole of the inner surface has been wetted and the chloroform is then squirted back into the bottle. By moving the plunger in and out a few times all chloroform is expelled and the syringe is dry and for all practical purposes sterile. I have used this simple method for some thirty years and have never had cause to regret it. As the whole procedure takes about a minute the time saved is considerable.

The chloroform bottle will be found useful in a variety of other ways—for rapidly sterilizing the clinical thermometer, the business end of an abscess incise dissecting forceps, probe etc. and for removing the remains of rubber adhesive plaster from the skin and grease stains from one's clothes. I may add that a few drops of chloroform judiciously applied to one's outer garments will cut short the activities of a flea that has reached one's skin—I am, etc.,

J SMALLEY

Torcross Devon May 16

Major IMS (ret.)

\* In our correspondence columns five months ago (January 8 p 92) Dr Charles Corfield said he thought that chloroform should be a good solution to keep both syringes and needles in, in the belief that chloroform is lethal to all forms of micro organisms and to spores. Professor L P Garrod who has made a special study of the action of antiseptics wrote in the *Journal* of February 12 (p 358) that the statement that chloroform will kill spores requires emphatic contradiction. He quoted the observation made by Koch in 1881 that chloroform would not kill anthrax spores in 100 days and his own observation that it kills the spores neither of *B. subtilis* nor of *C. tetani*. In the annotation which gave rise to the recent correspondence on the sterilization of syringes we drew attention (*Journal* April 30 p 955) to a case in which the patient died from gas gangrene after an injection into the thigh of luminal *C. welchii* were found in the 70 per cent alcohol in which the syringe was kept. It was pointed out that spores have been found in material which had been immersed in spirit for twenty years. It seems therefore that although many practitioners have used alcohol for sterilization of syringes without any accidents and although some evidently have had the same experience with chloroform it is quite clear that neither of these agents has a destructive effect upon spores and that anyone using them should bear this in mind—Ed. B.M.J.

### Penetrative Power of Infra red Rays

SIR—Advertisements of the Heala ray apparatus claim that it produces infra red rays of wave lengths between 600 000 and 1 000 000 Å and that these rays penetrate the tissues deeply. Now a number of scientific papers have been published which show that the shortest infra red rays (about 10 000 Å) and the red rays are the ones which penetrate the skin most deeply but only about

10 per cent of these penetrate through the cheek which is about 5 mm thick. In the case of a white man a faint red glow may be seen in a mirror in a dark room coming through the cheek when a glow lamp is put inside the mouth. Dr H J Taylor working in the laboratory of the St John Clinic found that the whole skin of a rat 0.41 mm thick absorption was complete for rays below 70 000 Å. The human body itself is an emitter giving out infra red rays of about 93 000 Å. An average length of 600 000 to 1 000 000 Å would then be felt as cold. The Heala ray apparatus is an emitter of dark heat and scientific evidence shows that heat when passed from a dark electric heater through a piece of flesh slowly conducted through from the surface. The rays do not penetrate it—I am, etc.,

LEONARD HILL

### Pathogenesis of Bronchiectasis

SIR—I was interested to read the paper by D S F P Lee Lander and Maurice Davidson in the *Journal* of May 14 (p 10-7). When I was working in the chest service of the Barnes Hospital St Louis I was able to make similar observations and noted that not only do the ectatic bronchi constrict during expiration but also that they dilate considerably when amyl nitrite is inhaled. Professor Ewart A Graham suggested that amyl nitrite might be given to patients who were having bronchograms made for the diagnosis of bronchial neoplasms and we observed that in some of these cases considerable dilatation occurred at the tumour site after the inhalation of the nitrite suggesting that there was bronchial spasm. When these observations were extended to cases of bronchiectasis it was found that in some cases dilatation occurred in the ectatic bronchi after inhalation of amyl nitrite. As the authors of the recent article point out this does not well agree with the textbook theory of the pathogenesis of bronchiectasis—I am, etc.

### Excision of the Patella

SIR—In the *Journal* of February 19 (p 297) there is a reference to an operation performed by Lister only years ago—Lister put his faith in the value of the antiseptic method to a supreme test. To Lister it was no less than he had opened joints before the first knee joint being a suppurating one. There the annotation leaves Lister and warns 'any and every one who calls himself a surgeon that they may come to grief over any operation involving opening of the knee joint. The dangers returned to are intra articular haemorrhage and infection. This is very sound advice to the surgeon of to day who operates full of hope but not certainty. Why was Lister's antiseptic method with drainage which had survived a 'supra test' not recommended? We have only to turn back to the second volume of the *British Medical Journal* of 1889 (p 355) to read of a number of cases of successful repair of the fractured patella reported by Lister. Incidentally only under very exceptional circumstances would Lister have excised the bone however severely damaged. He was decidedly averse to sacrificing tissues that could be saved. Damaged tissue that is excised is dead and cannot be saved by the antiseptic method and the patella is an important protector of the knee joint. It is not too much suggested that 'this cherished bone the patella is superfluous'. All second bones are precious and a knee joint without one is left vulnerable to the simplest

adjuvant treatment in cases of gonorrhoea provided it is given in appropriate doses.

2 More research is needed in standardizing the proper doses necessary for treatment in the different stages of gonorrhoea.

3 Local treatment in all stages of gonorrhoea is very essential.

4 The cases which best respond to the antitoxin are those with metastatic localizations.

5 The fact that there are cases which respond very quickly to the antitoxin and others which do not points to the need for further investigation to settle the contradictory views held by different workers. Owing to the well known fact that there are different species of gonococci which even of old differed in their response to treatment we believe that there may exist a species specificity to the antitoxin—a hypothesis which points to the line of investigation that could possibly be followed to settle this problem.

We intend in the near future to publish details of our work which we hope will further tend to prove the points stated above.—We are, etc.,

### Treatment of Placenta Praevia

SIR—I feel impelled to reply to the letter of Dr H Gordon Oliver (*Journal* May 14 p 1071) because I disagree entirely with his method of treating placenta praevia which is none other than the dangerous and one had hoped obsolete method of *accouchement force*. The first principle in the treatment of placenta praevia is that the case should be transferred to a hospital or well equipped nursing home whether the case requires Caesarean section or not. I am sure Dr Oliver agrees with this and my criticism only concerns his treatment of a case when it was not possible to send to hospital. Under these conditions the usual procedure is version and pulling down a leg, the delivery then being left to nature. If possible an external version is preferable but otherwise a bipolar version will be necessary. Under domiciliary conditions this treatment by early version and slow delivery gives good results although the use of Willett's scalp forceps provides an even better method. The technique of their use is easier than that of version while the results are as good for the mother and a little better for the child. I see no reason why the use of Willett's forceps should not be within the repertoire of the practising obstetrician who may have to deal with placenta praevia in isolated surroundings.

For lateral placenta praevia rupture of the membranes may be all that is required but the application of Willett's forceps in addition can do no harm and is a safeguard where the simpler measure fails to stop the bleeding. The risk to the child is a secondary consideration in such a serious maternal complication. Many of these children die owing to the original separation of the placenta and many of them are premature. Even with Caesarean section there will be a foetal mortality of about 25 per cent although isolated series with lower rates have been reported. Version gives a 60 to 70 per cent foetal mortality and Willett's forceps 10 to 15 per cent less than this. As regards the treatment actually adopted in Dr Oliver's case—namely manual dilatation and forceps delivery—the risks of severe laceration of the lower segment are extreme partly from manual dilatation and partly from the application of forceps when the cervix was sufficiently dilated to allow it. Such practice leads

to fatal post partum haemorrhage. It is in fact *accouchement force* and although it may give a slightly lower foetal mortality than version it will also result in a serious increase in the maternal death rate. The method is an old one dating back to before the time of Pare. It is rediscovered from time to time but has been proved to be not dangerous and should have no place in modern obstetrics. At the present time cases of this type or placenta praevia when removal to hospital is out of the question are best treated by version followed by natural delivery or if the instrument is available by the use of Willett's forceps—I am, etc.

### Origin of Cancer

SIR—I am much obliged to Dr W. L. English (May 14 p 1070) for drawing my attention to some points mentioned in the *Journal* of May 7 (p 1024) which apparently require amplification. In the case of the clock weight although the gravitational pull on the weight is almost the same all the way down the capacity for doing work is potential is greatest when the weight is at the top. I am however alive to the fact that the analogy between the clock and the tumour is not as good as it might be. In regard to the suggestion that the developmental energy I mentioned is of the same ilk as vital to cells *force hypermechanique* I can assure Dr English that far from being a vitalist I have been all my life a confirmed rationalist. In this connexion I suggest that he carefully peruse a discourse delivered by Professor H. Mark at the Royal Institution and published in *Nature* of July 3 last on the synthesis of large molecules. Professor Mark explains how for the building up of a highly complex organic molecule from a simple one a certain definite amount of activation energy is necessary. I am now suggesting that possibly the activation energy which Mark says is necessary for polymerization is of the same class as the growth energy or *Baumum* of Cope and other thinkers. Cope in his *Primordial Forces of Organic Evolution* (p 481) states: "The duration of life or of the functioning organic machine has a definite limit in time. All this means that a certain limited quantity of energy is at the disposal of each individual organism"—I am, etc.

E. G. FLETCHER

### The Services

#### DEATHS IN THE SERVICES

Surgeon Captain Sir ARTHUR STANLEY NANCE, K.B.E., C.B., R.N. (ret.) died at Donemark, Bantry, Co. Cork, on May 11 aged 77. He was born on May 27 1860. The son of Mr James Nance, F.R.C.S., of Ecclehall, Salterford, was educated at Trent College and St. Bartholomew's Hospital and took the M.R.C.S. in 1882 and the L.S.A. in 1885. After holding the post of House Surgeon at the Metropolitan Free Hospital he entered the Navy and became Fleet Surgeon of August 1900 and Surgeon Captain on June 22 1917. During the war of 1914-18 he was principal medical officer at the Admiralty and received the C.B. and K.B.E. in 1919 also the United States Navy Cross. He was a Justice of the Peace for Co. Cork. In 1896 he married Janet Beatrice daughter of Mr W. S. Tidball, B.A.

Colonel GEORGE JENOME KELLIE, B.A., M.D., Surgeon (ret.) died at Guildford on May 10 aged 70. He was born at Karachi on March 15 1867. The son of Mr James Kellie of the 9th Foot (Royal Irish Rifles) and was educated at King's College, London. He took the L.R.C.P. and the M.R.C.S. Eng. in 1890 and the D.P.H. of the Inst.

Lieutenant Colonel John Joseph OBE FRCGS (ret) died at Fairfield, Warrington, North Merseyside, on April 24, aged 67. He was born on March 7, 1891, at Lymm, educated at Gillingham, where he graduated M.B., B.S., with high commendation, and winning the Bursary Entrance Scholarship. Subsequently he studied at St. Bartholomew's Hospital, London, took the M.R.C.S., F.R.C.P. in 1918, and the F.F.C.S. in 1908. After filling the posts of house surgeon at Gillingham Hospital, Wakefield, and the Eye and Ear Infirmary at Liverpool, Stanley Hospital at Liverpool, he entered the Indian Medical Service as lieutenant on July 27, 1919. He became a major, lieutenant colonel on January 28, 1919, and retired on July 10, 1929. He served in the war of 1914-18, and was mentioned in dispatches in the *London Gazette* of December 25, 1917, and June 8, 1919, and received the OBE on June 9, 1919. Most of his service was passed in civil employ in Bengal and Bihar. He had been a member of the British Medical Association since 1901.

## A SUICIDE'S INSURANCE POLICY

### *Judgments in Final Appeal*

<sup>1</sup> Beresford v Royal Insurance Co Ltd *Times* May 10, 1937,  
53 *Times Law Reports* 583

To the Honorable Secretary of the Department of the Interior  
 Washington, D. C.  
 Sir: I have the honor to acknowledge the receipt of your letter of the 10th inst. in relation to the application of the National Park Service for the purchase of the land known as the "Horse and Rider" land, situated in the State of California, and to inform you that the same has been referred to the proper authorities for their consideration. I am, Sir, very respectfully,  
 Yours very truly,  
 J. M. Smith, Secretary

To Mr. Justice Macmillan, it was clear that it was not the duty or intention of the company in making its policy, to effect an assignment to itself. It was directly contrary to it, merely that the policy would do it, should and being its own, should permit of two operations. It did not cease to pay a consideration of his contract, should but in consideration of that it paid the premium, imposing a time limit of a year, it provided some sales and against his terms, out of policy, the policy to provide. Moreover, the insured could not be said to be cut by his crime. The intent of the provision was a transfer not a guarantee against the desire to benefit relative or creditors was a motive for it. If the plea of public policy was stated in this case the remarkable result would be that the company who had provided the insured with the inducement to commit a crime, would be the only persons to benefit by it. Two principles of public policy were in conflict, for it was undeniably public policy that persons should fulfil the contracts into which they entered, and in particular it was important that life insurance policies, which were most useful instruments of credit, should not be subject to any contingent invalidity. However having pointed out these considerations, it was the judgment in which the other learned lords had concurred. Lord Macmillan did not find that they were sufficiently convincing to deter him from agreeing with that judgment also.

The Irwell Valley Water Board were ordered by the Manchester Assize Court 1st December' to pay damages to a married couple who rented a public house supplied with water by the Board and had suffered from lead poisoning. The water was pure up to the stop cock of the premises, but on the premises themselves there was twenty four feet of old piping which was apt to contaminate water which stood in it. The water had a plumbo solubency of twenty eight parts in a million and Mr Commissioner Henn Collins, K.C. (now Mr Justice Henn Collins) found that although they had satisfied their statutory duty of supplying pure and wholesome water, they had failed in their common law duty of warning the consumers to take precautions against lead poisoning. The Board appealed but the Court of Appeal dismissed their case on May 5. Lord Justice Greer said that the Board had been warned over and over again that the water passing through the old pipe was liable to be contaminated, and they therefore had a duty to supply the water to the tenant in such a condition that after going through the pipes, it would be reasonably fit for domestic use. They might quite easily have protected the consumers either by making the water more alkaline and so reducing its plumbo solubency, or by

<sup>1</sup> *British Medical Journal*, 1938, 1, 100

sending out a circular to the users warning them to run off a certain quantity before they used it. The Board had delayed in unreasonably long time in installing apparatus which would have made the water harmless and had not sent out warning notices. They could not excuse themselves by saying that the local authority had advised them that it might be dangerous to frighten people by sending out these notices. Between 1929 and 1935 they had received a series of complaints of lead poisoning from various occupiers of premises. The Commissioner's decision was correct. It would be lamentable if the law did not protect consumers of water against this danger. The other learned judges agreed and Lord Justice MacKinnon pointed out that in 1902 the Local Government Board held a lengthy inquiry into the plumbic solvency of moorland water and that as a result various local Acts obliged water authorities to counteract this danger—for example the Acts governing the water supply of Mallock, Chertfield, Wakefield, Plymouth, Windermere, and Stockport. The court gave the Board leave to appeal to the House of Lords.

### A MOCK TRIAL "FEATHER v. WATSON"

The Court of King's College met on May 4 to try the important and interesting action of Feather v. Watson. It was convened by the Listerian Society of King's College Hospital and Judge Earengay presided, assisted by Dr Charles Newman the Vice-Chancellor. Counsel in the case were Mr. Max Muller and Mr. David Karmel.

Mrs. Feather was a disgruntled ex-patient bringing an action against her general practitioner, Dr. Watson, for negligence. Her case was that she consulted him on January 15, 1937, complaining of tiredness, nervousness, and palpitation. She was living apart from her husband. He diagnosed nervous depression and advised her to go for a cruise. This she did and on January 30 sailed in the *Empress of Abyssinia*, but she had a miserable time and returned in an even worse state of health. The sea had been very rough, she had been sea-sick, she had been frightened of Spanish warships in the Mediterranean, and on the voyage home had fallen down when the ship was rolling and hurt her head. Dr. Watson then told her to stay in bed, but as soon as she was well enough to get up she went to a specialist, Dr. T. S. F. West, whose name had been given her by the ship's surgeon, Dr. Maitair MacLagan. The consultant said she was really suffering from Graves's disease and called in a surgeon who performed a subtotal thyroidectomy on February 22. She made a good recovery, and on April 1 was reconciled with her husband. She sued the doctor for negligence in not diagnosing thyrotoxicosis and for prescribing a wholly wrong treatment. She claimed the cost of her voyage, her operation, and her specialist's fees, and also damages for physical and mental suffering.

The plaintiff explained giving evidence on her own behalf that she had always been highly strung. Since separating from her husband in 1935 she had become more nervous and had lost weight. Her eyes were not prominent before 1937. She told Dr. Watson she was tired, run down, nervous, and had palpitations. On her return she was in bed for a fortnight under his care, but he seemed very casual. Dr. MacLagan, who examined her on February 1, said he had noticed a very rapid pulse and slight exophthalmos and had taken her for a known case of exophthalmic goitre sent for a voyage before operation. He was surprised that Dr. Watson had not written to him. He did his best to keep her in bed, but she got up and did more than he would have advised. She was very sea-sick, ate nothing, and lost weight. He told her she was suffering from thyrotoxicosis. He mentioned the name of Dr. West when she asked him for a recommendation, but did not mean to go behind the defendant's back. Cross-examined, he said that no Spanish warship ever came in sight.

Dr. West said that Mrs. Feather on February 24 had obvious severe hyperthyroidism, slight exophthalmos, wasting

tremor, some enlargement of the thyroid, a pulse rate of 110 and a blood pressure of 145/75 mm. Hg. She needed an operation at once and must have had Graves's disease in January. He would have expected Dr. Watson at least to take the blood pressure and to see whether the rapid pulse was transient or permanent. Mr. M. C. Gunter, the surgeon, said that the patient had obvious signs of exophthalmic goitre, though the eye symptoms were not severe. He had the basal metabolic rate estimated and found it was -55 per cent.

### THE DEFENCE

Dr. Watson, giving evidence in his own defence, said that when he first saw the plaintiff she was nervous with very brisk reflexes, very volatile, and had no exophthalmos, but a little tachycardia. There was no obvious thyroid enlargement, and he did not think she had Graves's disease then. Her neurotic temperament and matrimonial troubles were quite sufficient to account for her symptom. He thought of Graves's disease as a possibility, but did not regard it as sufficiently probable to justify him in putting her to the expense of investigation. He admitted that he did not take her blood pressure, but said that it would not have told him anything. In his opinion her anxiety about the Spanish warship had brought on the Graves's disease. She had mild symptoms when he returned. He thought she should have rest in bed before the vessel reached.

Sir Thomas Standstill, an expert on thyroid disease, said that a mild degree of thyrotoxicosis such as in the present case was very difficult to diagnose. The symptoms of simple neurosis and mild hyperthyroidism were practically the same: nervousness, loss of weight, tremor, palpitations, and rapid pulse. A sea voyage was admirable treatment for a mild case of Graves's disease.

Judge Earengay, in summing up, pointed out that to the jury to return a verdict of negligence the matter must be all new. The doctor had done less than was reasonable, one might say, a prudent man in his position. They must not expect him to use the same skill and care as a specialist. The must judge him by the standard of a general practitioner and take all the circumstances into account.

The jury returned a verdict for the plaintiff with damages thirty guineas, the price of the cruise. The audience was asked to return a verdict by a show of hands and found an overwhelming majority in favour of the doctor. Judge Earengay said that the trial had been conducted very much as it would have been in court, and that those who had taken part in it and seen it might perhaps have been helped to understand the way in which such actions were tried. Doctor Watson was apt when they first came into court as witnesses to be pulling about, they received in cross-examination, but soon got used to it. As parties to an action they were told in being much more anxious for no one could tell how a jury would do. Every doctor should be afraid of the law, belonging to a deterrence society.

### A DOCTOR VINDICATED

After hearing evidence in the case of Perry v. Perry and Ciapparra, a special jury found that Dr. S. G. P. Ciapparra, the respondent, was not guilty of adultery. The petitioners' husband alleged adultery on three occasions at the doctors' surgery in Princess Road, Holland Park, and claimed damages. Both sides called private detectives, and the petitioner relied also on the evidence of his wife who wanted to adduce. The President (Sir Boyd Merriman), agreeing with the verdict, pointed out that they had found not merely that adultery was not proved, but also that it had never taken place. He said that there were at least four reasons which seemed to him absolutely conclusive against accepting the allegations. He dismissed the petition and awarded costs to Dr. Ciapparra. In exempting the jury from service for five years, he thanked them warmly and said that the services of a jury had been exceptionally valuable in that case.

## Obituary

### SIR THOMAS FLITCROFT

This well-known and popular Lancashire doctor died on May 14 at the age of 77, in Bolton, the place of his birth, to which he had given a long life of devoted service.

Thomas Evans Flitcroft received his medical education at Glasgow and at the University of Manchester. He held the offices of surgeon to the Bolton Infirmary and to the Edgeworth Homes. While he built up a large practice he was making for himself a reputation in municipal and national politics. A strong Liberal of the old school, who took his politics seriously, he was for long president of the Bolton Liberal Association. He entered the Town Council in 1892 and sat on it for twenty-six years during which time he filled many important positions there, being Mayor from 1926 to 1928. He served for several years on the Asylums Board for Lancashire, and was a Justice of the Peace for Bolton from 1899 to the time of his death. He took a keen interest in the Red Cross movement, and was for long assistant county director for the society. In Masonry he was a prominent local figure, and there were in fact few local public movements in which Flitcroft could not be found playing an active part.

Sir Thomas was at one time president of the Certifying Factory Surgeons Association. He was at different periods president of the Bolton and District Medico-Ethical Society, president and treasurer of the Bolton Medical Society, and chairman of the Panel Committee. During the war he was chairman of the Recruiting Committee and of the local Medical War Committee. He joined the British Medical Association in 1884, and during his long membership served as chairman of the Bolton Division from 1910 to 1920, representative in the A.R.M. from 1910 to 1919, president of the Lancashire and Cheshire Branch, 1912-13. Centrally, he was a member of the Parliamentary Elections Committee from 1919 to 1933, and served also on the Finance Committee, 1919-20.

Flitcroft was essentially a Lancashire man in general and a Bolton man in particular, and became a popular figure in his beloved county. During the struggle over the national health insurance scheme he became known to a much wider circle. Always an active politician (he unsuccessfully contested the Farnworth Division in 1918), he had a personal acquaintance with Mr. Lloyd George, who consulted him on the medical aspects of his scheme. This position of influence was not without its dangers at a time when medical and political feeling ran high. Flitcroft never concealed the fact that he was a strong believer in the scheme, though he did not fail to point out to Mr. Lloyd George that many modifications would be needed before it could be acceptable to the profession. However, though Lancashire was on the whole hostile to the scheme, Flitcroft never lost the confidence of his constituents as was proved by his return as the Bolton representative all during the fight and as long after as he cared to hold the office.

He was knighted in 1913 and thoroughly enjoyed the distinction and the pleasure it gave to his friends. This was shared by his wife, as popular a personality as he was himself, and a great helpmeet to her husband. It is pleasant to recall that before her death they celebrated their golden wedding. For the past few years his health had been failing and he took little part in affairs. His

funeral was very largely attended by representatives of every section of the Bolton public, including representatives of the B.M.A. and the other local medical bodies.

Dr. Alfred Cox writes

Flitcroft was a man of a very friendly disposition and exceedingly pleasant to meet at any time. With all his geniality he could be depended on for sound common sense, together with an understanding of the difficulties of other people. He was one of those successful and prosperous men who are not spoiled by prosperity—rather improved. He was a public spirited man, full of loyalty to the Bolton people who had made him, and of desire to do what he could to serve them. This applies also to his work for his profession and the B.M.A. I saw much of him from 1913 onwards until I left my post, and he could always be relied on for any service the Association asked of him. For B.M.A. purposes Flitcroft was for a long time synonymous with Bolton. Along with my contemporaries and his Bolton colleagues I remember him with kindly and affectionate feelings, mingled with deep respect for the moral courage which he displayed during the Insurance struggle, when a more popularity hunter would certainly have taken a different line.

### PROFESSOR I. BOAS

Professor I. Boas, the distinguished gastro-enterologist, died a fortnight ago in Vienna at the age of eighty. His scientific career began when he became assistant to Professor Ewald at the Augusta Hospital in Berlin in 1885. Working in co-operation with Ewald he devised the test breakfast which laid the foundation for all later investigations on the chemical functions of the stomach. Though in recent years it has been to a great extent replaced by the fractional test-meal, the Boas Ewald test breakfast is still used in many Continental and American clinics. Boas was a brilliant clinician and soon gained the reputation of being the foremost gastro-enterologist in Europe. Students from all parts of the world attended his lectures and demonstrations, and his textbook on *Diseases of the Stomach and Intestines* was for many years the most popular work on the subject, passing through nine editions and being translated into many different languages. Boas was a tireless worker and wrote numerous valuable papers describing the results of his investigations. Perhaps his most important practical contribution to medicine was his discovery of the presence of occult blood in the stools in organic diseases of the stomach and colon. He continued to investigate the changes undergone by blood pigments in the alimentary tract until a few weeks before his death.

In 1898 Boas founded the *Archiv für Verdauungs-krankheiten* which came to be known as *Boas's Archiv* and was the first journal of gastro-enterology published in any country. In 1920 he founded the German Gastro-Enterological Society, which meets alternate years in Berlin and Vienna.

The advent of National Socialism made it impossible for Boas to continue his scientific career in Berlin. He was fortunate to receive an invitation to work in one of the hospitals of Vienna, where he continued to investigate problems connected with the porphyrins and published a number of important papers on the subject. He believed that he had devised a spectroscopic method by which it would be possible to distinguish the pigment derived from carcinoma from that derived from ulcer, but he died before he had time to describe the test. When finally political upheaval reached Vienna he recognized that the

end of his working life had come. Still full of energy and mentally alert as ever in spite of his eighty years he found peace with an overdose of vitamin D. In the death of Boas the profession loses a pioneer of gastro-enterology, a man beloved by his many pupils throughout the world.

A F H

### THE LATE MR FURNIVALL

Major W Guyon Richards IMS (ret) writes: I have read your notice of Percy Furnivall with warm appreciation. I first met Furnivall when dressing for Mr Morant Baker at Birt's; he was doing his second term of dressing. He not only created a number of records for penny tarthing, cycling, but was a first class boxer; he reached the final of the amateur heavyweight championship. Whenever I came home from India a visit to Furnivall's was an exciting joy to look forward to. He married Sir Henry Butlin's daughter Olive. Of all the men I have met no one made a greater impression on me than Furnivall, in spite of being sometimes extremely tired after a busy day there was always an immense joy in life and a great interest in every subject one could bring up. His language was free and vigorous and one enjoyed being cursed by Percy. He once said that when you could call a pal any name you fancied and he enjoyed it you were really firm friends. I count Furnivall's friendship as one of the great things in my life.

Supplementing the obituary notice of Dr EVAN WILLIAMS RICHARDS (May 14 p 1078) we have received the following tribute from Dr W H Lewis, chairman of the Public Health and Housing Committee of the Montgomeryshire County Council. During the years that Dr Richards was medical officer of health and school medical officer for Montgomeryshire it was my privilege to be in close association with him and he inspired in me an affection and regard which will be with me always. His fine character and attractive personality were outstanding and made a responsive appeal to all who came in contact with him; notably his colleagues in the profession and all associated with him in his work. In truth it may be said that all men spoke well of him. The schoolmasters and the children looked forward to his visits in pleasant anticipation. The interest he had in his work and his full and precise knowledge of the details concerned with health matters and his administration were impressive—the retentive memory he possessed was extraordinary—a very special gift. During his last illness the total termination of which he foresaw, his bearing bore out all that his good life had fore-shadowed. His burial service at his beloved Tregaron, the place of his birth, was attended by many of his friends in the profession and it seemed as if the whole town was there to pay the last tribute. I am one of the many who mourn with his widow and children the loss of a great friend.

The following further particulars have reached us of the career of Dr MICHAEL GRABHAM who died at Quinto do Val, Madeira, on April 30. He was educated at the University College School, London, at St John's College, Cambridge, where he was an exhibitioner and took first class honours in the Natural Sciences Tripos and at St Thomas's Hospital. He entered the Government Medical Service, Jamaica, in 1891 and for thirty-eight years was in charge of the Victoria Jubilee Hospital, Kingston. During this time more than 400 maternity nurses were trained there for the colony. He was secretary of the Jamaica Medical Council in 1894, on the Board of Governors of the Jamaica Institute in 1902, president of the Jamaica Branch of the British Medical Association in 1927, served on the Cattle Diseases Commission in 1897 and the Malaria Commission in 1908, and received the thanks of the Jamaica Government for valuable services rendered at the earthquake in 1907. He was Masefield medallist in 1918, and retired in 1929. Dr Grabham

published many papers on obstetrical subjects in Government reports also on malaria and hookworm disease. He contributed many notes on the mosquitoes of Jamaica and much material for study to the Carnegie Institution in Washington, D.C., which has been incorporated in *The Mosquitoes of North and Central America and the West Indies*, published by that Institution in 1915. (After the great earthquake he received a cable inquiring for the area, not of himself, but of his collection of mosquitoes, suggesting that it was too valuable to be kept in an earthquake zone, but should be placed in safe custody in the museum.) A genus of more than forty species of mosquitoes bears his name. In 1934 he published *Plants Seen in Madeira* and another botanical work on the Madeira flora is now in the press.

Dr CYRIL JAMES GOZNEY EXLEY, who died at Bardney, Lincoln, aged 47, was born at Leeds and practised there after qualifying L.M.S.S.A. (Lond.) in 1915 until he moved to Bardney. He was trained at University College, London, and at the Leeds Medical School, and joined the Leeds Division of the British Medical Association in 1917. A colleague writes: Cyril Exley was a people's doctor in the best sense of that term. To rich and poor alike he brought the same genial presence, the same fund of humour and a vivid kindness and understanding of heart which made everyone feel eternally in his debt. He did his bit in the war and after coming to Bardney appeared to have before him long years of service. Unfortunately about three years ago his health broke down and two subsequent operations set a limit to his to-morrow powers. For this period of time he has borne about with him not one but several thorns in the flesh, which might well have broken the spirit of many a stronger man. Perhaps the impression of him which will linger longest in the memories of his friends will be his amazing fight he put up to carry on his practice. No more gallant effort to retain his usefulness could be imagined on the part of any man. Worn out by pain and general illness he tried to see his patients up to the last until suddenly he was compelled to quit the arena. Amidst grievous difficulties and disabilities he bore aloft unsullied the banner of the great traditions of medicine.

The Stratford Division of the British Medical Association has lost a tried and trusted member in the death of Dr R. BOYD ROBSON, which occurred on May 3 at the age of 63 years. He graduated M.B. Ch.B. at Aberdeen University in 1902 and was subsequently in practice at Ilford for thirty years, where he too, an active part in local affairs. He was a member of the staff of the Ilford Emergency Hospital (later to become the King George Hospital, Ilford) and honorary anaesthetist to the latter hospital. Dr Robson was also a member of the Executive Panel Committee and lecturer to the St John Ambulance Brigade. He was on active service during all four years of the great war, being in the campaigns in Gallipoli, Italy, and France.

Dr FRANCIS FERGUSON KERR, formerly of Manchester, died at the age of 77 in a London nursing home on May 10. He was born at New Bandon, New Brunswick, where his father, James Kerr, was the local magistrate and was educated at Ottawa Collegiate School. He followed his brothers into Western Canada, and was being opened up and eventually settled down in Winnipeg, then a small town, as a schoolmaster. When the Manitoba Medical School was started by local doctors he became one of the first batch of medical students and then went on to pursue his studies at Edinburgh University, where he graduated M.B. Ch.B. in 1898 and M.D. in 1903. He was a demonstrator of anatomy under Sir William Turner and after an assistantship in Haddington went into general practice in Horwich, Lancashire. After a few years he moved into Manchester, where he had a large general practice extending from Higher Broughton to Prestwich. He was a keen member of the British Medical

Association and took a leading part in the formulation of the well-known 'Salford scheme' when the Insurance Act was instituted. He was a prominent figure in Manchester medical circles, and many young doctors there owe much to his encouragement and advice. When the war was over many years of strenuous work had begun to tell on his health and he retired to San Remo, where he practised for a short time, but for some years past he had lived in retirement in a villa near St Raphael. He is survived by his widow, three daughters, and a son, his son a daughter, and two sons-in-law are all members of the medical profession, and two of his grandchildren are medical students.

We regret to announce the death on May 7 of Dr EDWARD SYMES PRIOR of Hampstead Way, Golders Green, N.W. He was a student at the Middlesex Hospital, and took the M.R.C.S. and L.R.C.P. diplomas in 1906, after which he served as house-surgeon to the "Dreadnought" Seamen's Hospital at Greenwich, house physician to the Brompton Chest Hospital, and resident medical officer at the Bolingbroke Hospital. During the war Dr Prior left his practice at Golders Green and went to Egypt to join the Egyptian Expeditionary Force, holding the rank of temporary captain R.A.M.C. On returning to civil life he was for some years a medical referee to the Ministry of Pensions. He had joined the British Medical Association in 1909, and was chairman of the Hendon Division in 1933-4.

## Medical Notes in Parliament

The House of Lords this week considered the Coal Bill. The House of Commons discussed air defence and the Board of Trade Vote and began consideration of the Finance Bill. Progress was made with other measures.

Dr Haden Guest has been appointed a member of a committee which is to examine the possibility of evacuating the population from areas of especial danger during air raids.

### Progress of Bills

In the House of Lords on May 23 the Children and Young Persons Bill and the Leasehold Property Repairs Bill, which had passed the House of Commons, were read a first time. The Workmen's Compensation (Amendment) Bill passed through Committee.

On the same day in the House of Commons the Housing (Rural Workers) Amendment Bill passed through the report stage. The motion for the third reading of the Bill was supported by Sir Francis Fremantle and was agreed to after a motion for its rejection had been negatived. The Bill was read a first time in the House of Lords on May 24.

Dr Elliot introduced the Mental Deficiency Bill in the House of Commons on May 24. The object of the measure is to extend by one month the time within which the Board of Control are required by Section XI of the Mental Deficiency Act 1913 to determine whether orders made under the Act are to be continued and to validate orders purporting to have been continued under that section. The Bill was read a first time without debate. The second reading will be taken on May 30.

A Select Committee of the House of Lords on May 24 rejected a Bill promoted by the governors of St Bartholomew's Hospital to enable them to use the general funds of the hospital for providing a paving patients' department.

### Insanity and Divorce in Scotland

The House of Commons Standing Committee on Scottish Bills began on May 17 to examine the Divorce and Nullity of Marriage (Scotland) Bill which had already passed the House of Lords.

On Clause 1 ("Additional Grounds for Divorce") Mr HORSBURGH moved to leave out the provision enabling the court to grant divorce on the ground that the defender was incurably insane. She said that if this ground were allowed divorce would be decided not on facts substantiated in court but on the opinion of experts. It could not be said with certainty that those who had been in an institution for five years would not recover. The Board of Control for Scotland in this year's report referred to a type of nervous illness regarded until recent years as incurable and fatal. For this a cure had been found. In the English law the petitioner had to prove that the person in an institution was suffering from incurable insanity. In the Scottish Bill incurable insanity was presumed after five years unless evidence could be brought to rebut that assumption. Great difficulties had been experienced in England. She had been in touch with the British Medical Association and she believed that in England the law would be a dead letter for the reason that it was almost impossible to get medical experts to declare that the illness of a person was incurable.

Major NEVEN SPENCE said he was utterly opposed to divorce for grounds of insanity. He had asked many alienists if they could draw up a list of incurable forms of mental illness. One and all declined to do so. Involutional mental illnesses affecting women at the menopause and rather later might go on for long over five years and be completely cured. Recovery from dementia praecox was not unknown. To-day thousands of general paralytics were going about doing their ordinary work. Sufferers from senile dementia recovered to an extraordinary extent under hospital treatment. All toxic confusional insanities were at least theoretically curable. The outlook for the puerperal cases, toxic delirium, and cases due to lead or alcoholic poisoning, was good but the illness might be prolonged beyond the five year period. As a physician wild horses would not drag from him a certificate of incurable insanity in any circumstances. He believed that to be the feeling of the medical profession as a whole. Mr ERSKINE HILL said the assumption in law would make the Scottish Bill more workable. Cures took place, for the most part in the first three years.

The LORD ADVOCATE Mr T. M. Cooper, said the chances of recovery for a married lunatic who had been at least five years in an asylum seemed to be in the ratio of 24 to 50. The medical expert was not necessarily the best authority on questions of this kind. Members should discard the suggestions of the medical experts and consider the question from the standpoint of the man in the street.

By 24 votes to 9 the Committee approved the retention in the Bill of the words 'is incurably insane.'

Consideration of the Bill was continued on May 19.

The Bill passed through Standing Committee and was reported to the House on May 24.

### Milk Tests in Scotland

Replying to Mr Tom Johnston on May 17, Colonel COLVILLE said that in the city of Aberdeen during 1937 354 test samples of milk, which were not formal samples taken for the purposes of the Food and Drugs Act, included 208 taken from a single herd at its owner's request, eighty seven out of the total of ninety five samples found to be under standard were from this herd. In the county of Aberdeen test samples were taken with the object of securing improvement in the quality of the milk from byres where formal samples already taken for the purposes of the Acts had been found to be under standard. In neither case, therefore, could a valid comparison with other areas be made.

Mr JOHNSTON asked if the Minister did not think that there was something seriously wrong when, in a county area, 56 per cent of the samples of milk taken were found to be adulterated. Colonel COLVILLE said that his answer indicated that there were special circumstances in this case.

Mr HENDERSON STEWART asked if the Minister had any reason to expect that adulteration of milk to an extent such as this was prevalent throughout Scotland. Colonel COLVILLE

replied that there was no information to support that general statement.

On May 17 Mr. JOHNSON asked the Secretary of State for Scotland why during 1937 no test samples of milk were taken for analysis in the counties of Buteshire, Orkney, Renfrew, Ross and Cromarty, and Zetland or in the parishes of Ar. Coubridge and Dumfries.

Colonel COLVILLE replied that although no test samples were taken in the areas referred to formal sampling under the Food and Drugs Acts was carried out. The Food and Drugs Acts did not impose on local authorities any duty to take test samples, although most local authorities took such samples as a means of obtaining a certain amount of information. He was called for or of assisting producers to detect the reasons why their milk was not up to the standard. An examination of the sampling reports for 1937 was being made by the Department of Health with a view to asking local authorities to increase their sampling activities where this appeared necessary.

Sir EDMUND FINLAY asked whether all local authorities could not be required to test milk. Colonel COLVILLE said that when the examination to which he had referred was finished they would see whether further steps were desirable in that direction.

### Nutrition for Expectant Mothers: Results of Scheme

In response to a request by Mr. Ward, Dr. Ellot circulated on May 19 this table showing particulars of the results of the Joint Council of Midwifery Nutrition Scheme for Expectant Mothers from July 1 to December 31, 1937.

Patients Receiving Special Foods					
Total number of mothers receiving food	Puerperal death rate from causes	Puerperal death rate from causes	Total puerperal death rate	Maternal death rate from causes	Infant death rate (still born and neonatal)
44-6	Nil	0.45	0.45	0.67	5
Patients Not Receiving Special Foods					
90-0	1.77	1.77	1.77	1.35	53

All rates in the tables are calculated per 1,000 of births.

### The Case of Bernard O'Sullivan

On May 23 Sir JOHN MELLOR asked the Home Secretary if his attention had been drawn to the evidence given at the trial of Bernard Anthony O'Sullivan who pleaded guilty to a charge of attempting to murder a boy aged 9, whether he had investigated the allegation of the medical officer of Brixton Prison that while at Broadmoor O'Sullivan had declared that he thought it right to murder young children, whether he was satisfied that O'Sullivan's record and condition justified his release in 1935, and whether he would take more effective steps to prevent the release of dangerous criminals and lunatics.

Mr. SORESENSEN asked a question on the same subject.

Mr. LLOYD replied that in March 1923 O'Sullivan was convicted of wounding with intent to murder and was sentenced to ten years penal servitude. While serving this sentence he showed no signs of mental abnormality and having earned by good conduct and industry full remission marks he was released in the ordinary course on licence on October 1930. In April 1932 he pleaded guilty at Manchester Assizes to a charge of larceny and was sentenced to three months imprisonment with the result that he became liable to serve in addition the remainder of his penal servitude sentence. At this time he was found to be insane and was transferred from prison first to Rainhill Mental Hospital and subsequently to Broadmoor where he remained until January 15, 1935 when his sentence expired. On the expiration of his sentence the powers and responsibilities of the Home Secretary with respect to his custody came to an end but as he was still insane he became liable to detention under the ordinary provisions of the Lunacy Law. Accordingly he was removed to the Broadmoor Mental Hospital as a rate-aided patient. The question whether and if so when the patient

should be discharged thereupon became one for the visiting committee of the hospital. Persons like O'Sullivan who are sentenced to one specified term of imprisonment or penal servitude were in a different position from persons who when charged with a criminal offence were found insane by the court and ordered to be detained during His Majesty's pleasure. When a person was ordered to be detained during His Majesty's pleasure the responsibility of deciding whether such a patient had sufficiently recovered to be released without undue delay rested on the Home Secretary. The decision in such a case was often a matter of great difficulty and great care was taken to make all necessary inquiries and to weigh the various considerations which arose. O'Sullivan was at present under careful observation in prison and it was a result of that observation he was certified to be insane immediately steps would be taken for his removal to Broadmoor.

### Bacteriological Standards for Graded Milk

Mr. LIDDALL on May 19 asked whether the Minister of Health was aware of the dissatisfaction felt by public health medical officers at the inadequate bacteriological standards for graded milks and of their anxiety over the absence of any compulsory bacteriological standard for ungraded milk which was consumed by the vast majority of inhabitants of the country, and what steps he was taking to remedy it. Dr. ELLIOT replied that bacteriological tests prescribed for graded milks were adequate as a standard of cleanliness. A similar standard for all other milk was not practicable at the present time.

### Annual Expenditure on Patent Medicines

On May 23 Mr. DAVID ADAMS reminded the Minister of Health that in 1937 a Select Committee of the House estimated that the amount spent each year in the United Kingdom on patent medicines was between £20,000,000 and £28,000,000 against an annual expenditure on drugs under the national health insurance scheme of only £2,000,000. He asked whether in view of this persistence of unskilled and often dangerous self-treatment the Minister would consider changes in the law whereby drugs sold under a proprietary name should at least be regulated as stringently as were ordinary foods and drugs under the Food and Drugs Act 1875. Mr. BERNAYS said he was not sure what change in the law Mr. Adams had in mind. Clause 6 of the Food and Drugs Bill now before Parliament not only strengthened the present law regarding labels issued with drugs, but also applied to advertisements containing false descriptions of drugs or misleading statements as to their nature, substance or quality.

### Experiments of the Hannah Institute

On May 23 Mr. MACQUISTEN asked the Minister of Agriculture whether his attention had been drawn to certain experiments made by a body called the Hannah Institute, assisted by contributions from the co-operative societies and a large milk combine by which the institute were alleged to have satisfied their elves that over 60 per cent of calves fed on fresh milk soon contracted bovine tuberculosis and what steps he proposed to take in view of those experiments.

Mr. MORRISON said he could not be expected to be responsible for the experiments of a scientific body. This was only one experiment and many others were being carried out. It would not be safe to go by that experiment within a narrow range. The Government was trying to review the whole subject in the light of other experiments as well as this one.

**Houghall Isolation Hospital.**—Mr. MESSER asked on May 19 if the Minister of Health had completed his inquiry into the administration of the Houghall Isolation Hospital. Dr. ELLIOT said he had received through the usual channels a report on the administration of this hospital. He had no authority to determine the points at issue between the Council and the former matron as to the conditions of re-employment. He was satisfied that the premises were excellent, quite unsuitable and he hoped shortly to receive a proposal to approve formally proposals already before him for its replacement by a new hospital.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended May 14, 1938

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland Median values for the last 9 years for (a) and (b)

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for (a) The 126 great towns (123 in 1937) in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns (9 in 1937) in Northern Ireland

A dash — denotes no cases, a blank space denotes disease not notifiable or no return available

## EPIDEMIOLOGICAL NOTES\*

## Smallpox

During the week under review a case of smallpox was notified at Gravesend and admitted to the Isolation Hospital. The patient referred to last week has since died.

## Enteric Fever

Notifications of enteric fever in England and Wales were 14 compared with 8 in the previous week with 1 death—the same as last week. One case was notified in London itself in the borough of Kensington. In Scotland 30 cases of enteric fever were notified compared with 41 in the previous week, of which 3 were cases of paratyphoid (Glasgow). Forty-four cases of typhoid fever were notified in Hawick and one each in Ayr County, Falkirk and Paisley. Of the 97 cases to date in the Hawick outbreak 2 patients have died. Following a suspected case of typhoid in one of the passengers of the Orient liner *Orema* which docked at Tilbury on May 19, 4 members of the crew have been sent for observation to the Port of London Sanitary Hospital at Denton near Gravesend.

## Diphtheria and Scarlet Fever

While the incidence of diphtheria in England and Wales is practically the same as last week more cases were notified in London—144 compared with 103—and there were 8 deaths compared with 3 in the previous week. The numbers for England and Wales remain above the median value for the last nine years and those for London remain below it. Scotland, Eire and Northern Ireland also report some increase in the incidence of diphtheria. There was a rise in the notifications of scarlet fever in England and Wales for the week—2154 compared with 2078—and in London the figure was 181, compared with 174 for the previous week. For England and Wales the notifications are above the median value for the last nine years, for London they are considerably below it. There was a slight rise in the figures for Scotland and Eire and a slight fall in those for Northern Ireland.

## Primary and Influenzal Pneumonia

Notifications of primary and influenzal pneumonia in England and Wales continue to decline, 1188 being recorded compared with 1222 in the previous week, for London the figures were 76 and 85 respectively. There were 34 (34) deaths from influenza in England and Wales and 11 (8) in London. Local rises in the notifications of pneumonia were as follows: Warwick 116 (111) of which 72 (75) were in Birmingham and 13 (15) in Coventry, while smaller numbers were reported widely scattered throughout the county. West Riding (Yorks) 133 (125) of which 65 (17) were in Sheffield and 19 (17) in Leeds and smaller numbers were reported from a large number of urban districts. During the week the deaths from influenza were: Birmingham 4 (4) Bradford 3 (0) Sheffield 2 (3) Coventry 1 (3). In Scotland notifications of primary pneumonia were 266 compared with 273 in the previous week. There were 11 cases of influenzal pneumonia, 2 more than last week and 3 deaths the same as last week.

## Measles

In the 126 Great Towns there were 28 deaths from measles compared with 32 in the previous week, of these 11 (13) occurred in London and 2 (0) in Gateshead and in no other area did more than one death occur during the week. During the week 343 cases were reported from the LCC elementary schools compared with 712 in the previous week. The average daily

admissions to the LCC fever hospitals were 49 an increase of 6 on the previous week while the number of cases of measles under treatment in these hospitals on Friday May 13 was 1630 compared with 1718 on May 6. On the same day there were under treatment in the LCC fever hospitals 1047 (10.6) cases of diphtheria, 77 (808) cases of scarlet fever, 285 (295) cases of whooping cough. Notifications for the week ended May 14 in the eleven metropolitan boroughs in which measles is notifiable were: 461 (406) distributed as follows: Battersea 16 (76) Bermondsey 18 (38) Finsbury 19 (23) Fulham 42 (57) Greenwich 126 (11) Hampstead 20 (17) Lambeth 36 (31) St. Pancras 37 (34) Shoreditch 39 (28) Southwark 21 (28) Stepney 27 (31). In Scotland 426 cases of measles were recorded compared with 461 in the previous week, the figures for Glasgow were 164 (186) Dundee 77 (96) Aberdeen 60 (71) Falkirk 37 (27) Edinburgh 36 (76). During the week there were 2 deaths from measles in the 16 principal towns of Scotland compared with 17 in the previous week, of these 9 occurred in Glasgow, 7 in Dundee and 1 each in Edinburgh, Clydebank, Coatbridge, Kilmarnock, Hamilton. In Northern Ireland there were 8 cases of measles, 5 of which were in Belfast alone, with 2 deaths, both in Lurgan. During the week there were 5 deaths from measles in Eire (all in Dublin).

## Typhus

During the week ended May 7 there were reported in Morocco 169 cases of typhus with 10 deaths compared with 168 cases in the previous week. The 169 cases were mainly distributed as follows: Chaouia 42 (48) Marrakech 26 (40) Rabat 22 (24) Casablanca 10 (1). Europe: Poland during the week ended April 30 there were 14 cases of typhus with 8 deaths compared with 103 cases and 8 deaths in the previous week, the departments with more than ten cases were: Lwow 25, Wilno 17, Polesia 16, Stanislawow 14, Nowogrodek 11, Wolhynia 11. In Rumania during the week ended March 23, 128 cases of typhus were reported compared with 160 in the previous week, occurring mainly in: Orhei 31, Lapusna 21, Covurlui 15, Balti 12. In Yugoslavia during the week ended April 24 there were 23 cases of typhus (35 in the previous week) distributed as follows: Drina 12, Litoral 9, Zeta 2.

## Universities and Colleges

## UNIVERSITY OF OXFORD

The following notice was published in the *Oxford University Gazette* of May 18:

## FIRST EXAMINATION FOR THE DEGREE OF B.M.

The Board of the Faculty of Medicine gives notice that the following regulations for human anatomy will be substituted on January 1, 1939 for those now in force (*Examination Statutes* 1937 p. 314):

## II Human Anatomy

The examination will include (a) a written paper and (b) a practical and viva voce examination. The written paper will be assigned to each part in the written examination and will be expected to show their acquaintance with the structure of the human body, including general topography, the skeleton, the main anatomy of organs and tissues, with special reference to processes of growth and development, and the structure of human embryos, and the external and internal anatomy of the human body. The viva voce part of the examination will be expected to show their knowledge of human anatomy, and to test their ability to recognize and describe the normal and abnormal anatomy of the human body, and to give evidence of their knowledge of the anatomy of the living body.

Dr R. H. S. Thompson has been elected to a Research Medical Fellowship and Practitioner in Medical Science at University College.

\* Except where otherwise mentioned figures in parentheses refer to those for the week preceding the one under review.

## UNIVERSITY OF CAMBRIDGE

At a congregation held on May 13 the following medical degrees were conferred

MD—T O Garland G H Jennings, W F Nicholson  
MB BChir—J H Waid

*Assistants in Medical Research*

The Appointments Committee of the Faculty of Medicine will shortly proceed to appoint three assistants in research to the Regius Professor of Physic to hold office for three years from October 1, 1938. (1) Assistant in research in radiology. This is primarily a research appointment but will include part-time duties as assistant in the x-ray department at Addenbrookes Hospital with opportunities for x-ray investigations in the Department of Anatomy. Salary £600 a year. (2) Assistant in research in psychiatry. This is primarily a research appointment but will include part-time duties as assistant in the psychiatric department of Addenbrookes Hospital with opportunities for work in the Department of Experimental Psychology. Salary £500 a year. (3) Assistant in research in pathology (morbid anatomy and histology). This is primarily a research appointment but will include part-time duties as assistant in the pathology department of Addenbrookes Hospital, with opportunities for work in the Department of Pathology of the University. Salary £500 a year. Applicants for these posts should hold the medical degrees of a university within the British Empire and should produce evidence of special training after qualification in radiology or psychiatry or pathology as the case may be. Further information may be had from the Secretary of the Appointments Committee of the Faculty Mr R Williamson Department of Pathology Tennis Court Road Cambridge to whom applications together with three testimonials a statement of previous appointments, and copies of published papers should be sent by July 1.

*The Oral Examination in Pharmacology*

Under the old regulations elementary pharmacology in the Second MB Examination Part III consisted of a practical and an oral examination. Under the regulations of October 1 1934 which came into force in March 1936 a longer oral examination was substituted, because a practical examination on the new course was not feasible. This examination has now been held four times, but has been unsatisfactory because in the case of some candidates it is difficult to assess their knowledge in an examination which is wholly oral. More over a wholly oral examination is not in accord with Regulation 17. The Faculty Board therefore proposes that a two hours paper in pharmacology be added.

## UNIVERSITY OF LONDON

At a meeting of the Senate held on May 18 the Dunn Exhibitions in Anatomy and Physiology for 1938 were awarded to S D V Weller of University College and J W L Doust of King's College respectively. The degree of DSc in Biochemistry was conferred on W T J Morgan.

## ST GEORGE'S HOSPITAL MEDICAL SCHOOL

Sir Frederick Hobday, Emeritus Professor Royal Veterinary College and honorary lecturer in comparative medicine to St George's Hospital Medical School will give a course of six lectures entitled 'A Comparison of Diseases in Animals and Man' in the Medical School on Mondays at 5 p.m., beginning on May 30. The lectures will be illustrated by epidiascope and cinematograph and are open, without fee to all medical and veterinary practitioners and students.

## LONDON HOSPITAL MEDICAL COLLEGE

Two open scholarships each of the value of £100 have been awarded to H G Danziger of Trinity College Cambridge and F E T Scott of Clare College, Cambridge for the academic year 1938-9.

A course of two lectures on 'The Physiology of the Digestive Glands' will be given at University College Gower Street WC by Dr B P Babkin, Research Professor of Physiology in McGill University Montreal on June 7 and 9 at 7 p.m. At the first lecture the chair will be taken by Professor C Lovatt Evans FRS. The lectures which will be illustrated with lantern slides are addressed to students of the University and to others interested in the subject. Admission is free, without ticket.

## UNIVERSITY OF DURHAM

At a meeting of the Council of King's College Newcastle on May 16 Angus E W McLachlan MB ChB, PhD Ed was appointed lecturer in venereal diseases in succession to Dr Sidney Thompson who has resigned.

## UNIVERSITY OF WALES

## WELSH NATIONAL SCHOOL OF MEDICINE

The Council of the School at its meeting on May 19 appointed Dr W H Tytler to the David Davies Chair of Tuberculosis to fill the vacancy caused by the retirement of Professor S Lyle Cummins on September 30 1938. Dr Tytler who graduated in medicine at the University of Toronto at present holds the post of Research Bacteriologist to the Welsh National Memorial Association.

## UNIVERSITY OF BIRMINGHAM

*Honorary Degrees*

At the annual degree ceremony on July 2 to mark the occasion of the opening of the Hospitals Centre and the new Medical School on July 14 by the King and Queen the honorary degree of LL.D will be conferred on the following members of the medical profession: Dr Robert Hutchison President of the Royal College of Physicians of London Sir Cuthbert Wallace Bt, President of the Royal College of Surgeons of England and Sir Edward Mellanby, FRS, Secretary to the Medical Research Council.

## UNIVERSITY OF LIVERPOOL

The Council at its meeting on May 17, appointed Thomas Benjamin Davis MD professor of pathology in the University of Bristol to the George Holt Chair of Pathology in succession to Professor J H Dible.

The title of Professor of Tropical Diseases of Africa was conferred on Dr Thomas Herbert Davis while holding the directorship of the Sir Alfred Lewis Jones Research Laboratory Sierra Leone, where he has served for nine years.

## UNIVERSITY OF MANCHESTER

Presiding at a meeting of the Court of Governors on May 17 the Vice Chancellor, Professor J S B Stopford, gave a survey of recent and forthcoming events. He hoped that it would very soon be possible to start work on the clearing of the site of the new dental hospital and that building would immediately follow. Work was proceeding apace with plans for alterations to the Burlington Street Drill Hall which was being made into a centre for physical recreation. In the new gymnasium rooms were being provided which could be used for carrying out tests of physical fitness and other forms of medical examination. He was hopeful that with the co-operation of the Medical School it would be possible not only to provide medical supervision and promote the physical welfare of students, but also to find out a good deal about health and the factors influencing health, that would be of preventive medicine. The Vice Chancellor mentioned among other developments in the University the proposed creation of a degree of Doctor of Dental Surgery, to encourage research and advance scientific study, and so help to lift dental surgery to its rightful place.

Dr E N Rowlands has been appointed assistant director of the Department of Clinical Investigations and Research and Dr Benjamin Portnoy chief medical assistant in the Department. Mr H T Simmons has been appointed lecturer in applied anatomy.

On May 18, at the Founder's Day commemoration the honorary degree of Doctor of Science was conferred on Sir Henry Dale, MD FRS, Director of the National Institute for Medical Research. In accepting the honour paid to him as a recognition of medical science, Sir Henry Dale said: 'Your University is rightly proud of its fine department for the basic sciences of medicine with the distinguished investigators who lead it. Only recently you took one of them from his teaching and researches and gave him the highest administrative responsibility as your Vice Chancellor. You have here a great hospital devoted to the medical care of the dense population which the industry has created around you. Here if anywhere are the conditions for the growth of a great centre of medical research in the fullest sense.'

## UNIVERSITY OF SHEFFIELD

At its meeting on May 13 the University Council received with regret the resignation by Dr W Skyrme Rees of the post of demonstrator in anatomy. The Council thanked Dr Rees for his services to the University.

## UNIVERSITY OF EDINBURGH

The honorary degree of LL.D will be conferred on Dr W N Robertson CMG CBE FRACS, Hon FACS Vice-Chancellor of Queensland University on July 20 on the occasion of the installation of Lord Tweedsmuir as Chancellor of the University.

## ROYAL COLLEGE OF SURGEONS OF EDINBURGH

At a meeting of the Royal College of Surgeons of Edinburgh held on May 14 with Mr W J Stuart President in the chair the following having passed the requisite examination were admitted Fellows

H R Arthur F G Bidder A L W Bell A Currie J D Davies V Drach N Dutt T E Elliot D Evans B S Gribble J R Gibbs G D Harris A R Hill S W Lissett E Lifford A Lvall J S MacViney P L O'Neill E Parry J C Patterson R B Peckham J P Philp F B Pierce J A Ross A G Rutledge S C Saptarshi T M Scott I D Sutherland R Thorny L E Vine J A Wain R A L Wenger H C Wyckoff

The Henry Arthur Dalziel Burns Bursary was after a competitive examination in organic chemistry in its application to medicine awarded to M Metz

The Baillie Memorial Prize was after a competitive examination in materia medica and therapeutics awarded to E Blumenkranz.

## SOCIETY OF APOTHECARIES OF LONDON

The following candidates have been approved at the examination indicated

MASTER OF MIDWIFERY—Herbert Reginald England M B B Ch Robert Stevenson Cromie M D Louis Alice Matheson M B Ch B DPH Sumitranbai Shinkhande M B BS DCOG

## Medical News

The King has appointed Dr Edmund Claud Malden to be Surgeon Apothecary to His Majesty's Household at Windor Castle in the room of Sir Henry L Martyn KCVO who has resigned

Sir William Bragg O M President of the Royal Society will open the Meyerstein Institute of Radiotherapy at the Middlesex Hospital on Thursday June 9 at 3 p.m.

The House of the British Medical Association including the Library will be closed for the Whitsun Holiday from 5 p.m. on Friday, June 3 to 9 a.m. on Tuesday June 7 (Library 10 a.m.)

The House and Library of the Royal Society of Medicine will be closed for the Whitsun holiday from Saturday June 4 to Monday June 6 both days inclusive

The Buckton Browne annual banquet of the Harveian Society of London will be held at Merchant Taylors Hall Threadneedle Street EC on Tuesday June 14 at 7.30 for 8 p.m.

The Chairman and Directors of Boots Pure Drug Company Limited are celebrating the jubilee of the firm by a luncheon party at the Savoy Hotel London on Thursday June 2 Lord Trent Chairman and Managing Director will preside and the principal guest will be the Minister of Health

In our advertisement columns this week the Senate of the University of London invites applications for the Chair of Radiology tenable at the Royal Cancer Hospital at a salary of £1,500 per annum

A meeting of the Kensington Division of the British Medical Association will be held in the Great Hall of B.M.A. House Tavistock Square WC on Friday June 24 at 8.45 p.m. when a symposium on Co-operation within the Profession will be opened by Sir William Wilcock Viscount Dawson of Penn Dr W A Daley (Principal Medical Officer LCC) Dr James Fenton (President Society of Medical Officers of Health) Dr G C Anderson (Secretary British Medical Association) Dr E A Gregg (Chairman London Panel Committee and Insurance Acts Committee) and Dr Alfred Cox (Secretary London Public Medical Service) will take part in the subsequent debate

The National Institute of Industrial Psychology's vacation course in psychological methods of vocational guidance will be held at the London School of Economics from August 3 to 13. During the same period and at the same place a vacation course in the administration of Binet Simon tests of

intelligence will also be held. The fee for the former course is five guineas and for the latter three guineas. Applications should be sent as soon as possible to the Secretary of the N.I.P. Aldwych House WC2

The German Tuberculosis Congress will be held at Zoppot on June 10 and 11 in connexion with the meeting of the medical officers of the German Public Health Service. Further information can be obtained from Reichstuberkulose Ausschuss Einemstrasse 11 Berlin W 62

The third Congress of the Italian Radio Neuro Chirurgical Society will be held at Pisa from June 4 to 6. Further information can be obtained from the president, Professor Avila Clinica delle Malattie del Sistema Nervoso Pisa

The thirteenth Congress of the International Association for the Protection of Childhood will be held at Frankfurt am Main from June 12 to 18. Further information can be obtained from the Secretariat Saalbau Jungnolstrasse Frankfurt am Main

The first Pan American Congress of Endocrinology which is also the first congress of endocrinology to be held in any part of the world will take place at Rio de Janeiro from July 17 to 23 under the presidency of Professor Aloysio de Castro. It will consist of four sections dealing respectively with the experimental clinical surgical and medico-social aspects of endocrinology. Further information can be obtained from the Academia Nacional de Medicina Avenida Augustus Severo 4 Rio de Janeiro Brazil

The twenty-ninth Congress of the German Röntgen Society will be held in Munich from July 4 to 7. Further information can be obtained from the president Dr G A Weltz, Ludwigstrasse 4 München 22

There has been set up in the Kaiserin Friedrich Haus Robert Koch Platz 7 Berlin NW 7 an information bureau which will be able to give doctors every kind of information. The office is semi-official and gives advice impartially and free of charge. It would be to the advantage of every visiting doctor to get into touch before or after his arrival in Berlin with the Kaiserin Friedrich Haus so as to save time and make the most of his stay

King Edward's Hospital Fund for London has just issued the May edition of the outpatient time table to all doctors in the London area. The object of the time table is to prevent as far as possible patients attending outpatient departments on the wrong day or at the wrong time. Further copies are obtainable free from the publishers Messrs George Barber and Son Ltd 25 Fumival Street EC 4

The April issue of the *Chinese Medical Journal* is devoted to the history of Chinese medicine

The issue of *Paris Medical* for May 7 which is devoted to diseases of the heart and vessels contains an appreciation by Dr H Grenet of the international congress on rheumatism recently held at Oxford Bath and London. The issue for May 14 contains the list of the consulting and resident staff of the Paris hospitals

To celebrate the fiftieth birthday of the American Association of Anatomists a portrait medal has been struck in memory of its first president Joseph Leidy (1825-91). This was designed by Robert Tait McKenzie Canadian physician and sculptor (now living in Philadelphia) of the work The Sprinter at Cambridge The Athlete at Oxford and the Scottish American War Memorial at Edinburgh are familiar examples on this side of the Atlantic

Mr Harry Oakes has made a gift of £60,000 to St George's Hospital and on May 19 was elected a vice president. A short time ago he gave £20,000 to the hospital

Dr J A Struthers (Inner Temple) was elected to the Bar on May 11

Dr Mohammed Mahtouz Bey principal medical officer ophthalmic section Government Hospital Alexandria has been elected President of the Ophthalmological Society of Egypt

## Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL BMA HOUSE TAVISTOCK SQUARE WC1

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, BMA House Tavistock Square WC1 on receipt of proofs. Authors overseas should indicate on MSS if reprints are required as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager. Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary BMA House, Tavistock Square WC1.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are

EDITOR OF THE BRITISH MEDICAL JOURNAL *Anology Westcent London*

SECRETARY, *Mediscra Westcent London*

The address of the BMA Scottish Office is 7 Drumsheugh Gardens Edinburgh (telegrams *Associate Edinburgh* telephone 24361 Edinburgh) and of the Office of the Irish Free State Medical Union (IMA and BMA) 18 Kildare Street, Dublin (telegrams *Bacillus Dublin* telephone 62550 Dublin).

### QUERIES AND ANSWERS

#### Mosquito Bites

'BS' writes: In the course of my holiday this summer I shall be visiting places where mosquitos may be expected. Is there any preparation one can apply to the exposed skin which will repel these insects? In the event of a bite what is the best immediate local treatment?

\*\* Some years ago the Medical Officer of Health for Belfast advised oil of lavender on the hair or clothes as a preventive of mosquito bites. "As the mosquito frequently bites about the ankles two pairs of thin socks or stockings are better than one thick pair." To protect the face use a 50 per cent alcoholic solution of thymol, or oil of cloves in lanoline. If bitten dab on at once a weak solution of ammonia or of washing soda or common soap and vinegar, or apply a cut onion to the sore. If the irritation is severe apply iodine in glycerin.

#### Menostaxis

Dr ALISTAIR FRENCH (Greenford) writes: I suggest that 'A H I' (*Journal* May 21, p 1142) should try a course of antuitrin S for his patient who would appear to have an endocrine imbalance. I c.m. subcutaneously twice a week for six to ten weeks should re-establish a more normal rhythm. This was successful in a recent very similar case of mine and I should be interested to hear the result from 'A H I' if he tries this treatment.

#### Income Tax

##### Temporary Residence in the United Kingdom

'A D' is a British subject and was resident in the United Kingdom until 1928. Since then he has resided and worked abroad (but was on leave in this country between June 15 and December 13 1933) up to May 7, 1937. He was in the United Kingdom from that date to January 15, 1938, and during that period terminated his appointment abroad. On the last mentioned date he sailed to take up another appointment and has been abroad since. On leave he received on departure a lump sum representing two months pay for each year's service. He holds shares in British companies and income tax is deducted from these on payment. He makes certain allowances to relatives.

\*\* 'A D' is apparently not liable to income tax in respect of his foreign earnings—it is assumed that the appointments abroad were not held from companies registered in the United Kingdom. As regards the dividends,

he is entitled to relief from the income tax—not to the allowances which would be made if he were resident in this country but to the proportion of such allowances in the ratio of his total income to his United Kingdom income (An application for the appropriate form of claim should be made to the Chief Inspector of Taxes, Waterloo House London SE1). A further allowance may be due on any income which arises abroad but is paid to him under deduction of tax because it is paid through an office in England. The allowances in question would include anything in respect of the payments made to relatives, provided that the relative concerned is 'incapacitated by reason of old age or infirmity'.

#### Allowance for Wear and Tear

'J C' inquires whether there is a statutory right to the additional 10 per cent.

\*\* Yes. Rule 6 of Cases I and II, Schedule D provides for such deduction as the Commissioners may consider just and reasonable. Section 18 of the Finance Act provides that the Commissioners shall allow an additional deduction equal to one tenth of the deduction attained under the said Rule 6. The present Budget proposes to increase the one tenth to one fifth and assuming it becomes law for 1938-9 where 20 per cent is considered just and reasonable the actual deduction due will be 20 per cent plus one fifth of 20 per cent—that is 24 per cent.

### LETTERS, NOTES, ETC

#### Elementary Ambulance Instruction

"FIRST AID" writes: There must be many practitioners like myself who having given lectures or conducted examinations in first aid, pray that it may never be their lot to be treated by their classes. I am sure that for the elementary first aid courses too much is taught in lectures and in the manuals. Too much stress is laid and time spent on the treatment of fractures. Surely it is unnecessary to know the Latin names for the bones. I have known pupils from elementary classes asked in their first examination what Potts and Colles' fractures were. While wise lecturers may tell them that the less they do to a fracture the better, they are expected in their examination to know how to apply splints and bandages. They cannot realize what damage and shock they may produce by inexperienced handling. I am told that the home nursing lectures are hardly practical and simple enough for beginners, and for those who will only have to nurse in cottages and small houses. I should be glad to know if others agree with me. The majority of those people to whom I lecture are easily confused, and the simpler we can make the subject the better.

#### Rate of Growth of Nail

Dr L W HEFFERMAN (Swansea) writes: On December 26 1937, an injury produced a small subungual hematoma of my right middle finger. The discoloration was just visible at the edge of the cuticle. I have seen it emerge into the open, and now, five months later (May 22, 1938) like the setting sun it is disappearing over the distal margin of the nail. The distance traversed has been 1.4 cm, this is the length of the nail from the cuticle to the cut edge. The nail has therefore grown 1.4 cm in five months.

#### Medical Pictures

A correspondent writes: The eleventh annual exhibition of the New York Physicians Art Club, which opened at the New York Academy of Medicine on May 7, is essentially conservative and conventional, the majority of the 170 paintings being the tangible result of a summer vacation's leisure and as such of no medical interest. Among the notable exceptions however are several abstractions which are certainly original. Dr M M Melicow's oil abstraction 'Exploratory Operation' depicts two surgeons stooping over a large recumbent question mark. In Dr F M Margaretten's painting 'Caesarean Section' famous figures in its history watch from the gallery a modern operation being performed. Among the photographs exhibited those by Gregory Zilboorg and by Max Thorek are particularly effective.

# EPITOME OF CURRENT MEDICAL LITERATURE

## Medicine

### 433 Misconceptions of Hilar Tuberculosis

F HAMBURGER (*Disch Tuberc bl* March 1938 p 55) deplors the mischievous myths which have grown up around the conception of tuberculosis of the bronchial glands. Strictly speaking it is a condition to be found in nearly all persons infected with tubercle bacilli by inhalation. In other words almost everyone who is tuberculin positive may be said to be the subject of bronchial gland tuberculosis. Yet this nearly always innocent condition has been exalted to the position of a real danger signal and radiological hilar shadows have been allowed to darken the lives of countless children who would have been both happier and healthier had they never been branded with this term. According to Professor Hamburger, the radiological demonstration of bronchial gland tuberculosis should be ignored unless tuberculin skin tests are positive the sedimentation rate is abnormally high percussion and auscultation sound a note of warning and the radiological examination itself shows something more definite than a hilar shadow. To condemn a child to months and even years of a valetudinarian life on the strength of only a hilar shadow and without other confirmatory evidence is not in the best interests of either the child or its parents. It often happens that a child is subfebrile suffers from a chronic cough and looks poorly but is definitely non-tuberculous as shown by the negative findings of a tuberculin test. A hilar shadow in such cases may be due to a non-tuberculous pneumonia which may clear up in two or three weeks. Were the clinical and radiological picture really due to tuberculosis a year or two would be needed for recovery.

### 434 Hemeralopia and Gastric Ulcer

T GANTZEL (*Hospitalsudende* January 18 1938 p 85) states that in 1931 the dietetic treatment of gastric ulcer at his hospital was changed from a restricted to a fairly liberal regime which began with milk and gruel and was extended in three or four days (after melaena pain tenderness and vomiting had ceased) to egg porridge toast and mashed potatoes. In order to ascertain the influence of this diet on the store of vitamin A in the body hemeralopia tests were carried out on admission and again after the completion of treatment some three weeks or more later. Of the forty four patients thus tested as many as thirty seven suffered from hemeralopia of various degrees on admission. On the completion of treatment nineteen showed a diminution of their hemeralopia twenty-one showed no change and four a higher degree of hemeralopia than before. Considering the comparatively high proportion of cases in which improvement was noted in the hemeralopia it would seem justifiable to conclude that the dietary was not faulty with regard to its vitamin A content. As other Danish observations have shown that the mortality from gastric ulcer is only about 1 per cent on this fairly generous diet the author concludes that its substitution is justifiable.

### 435 Primary Liver Carcinoma in Liver Fluke Disease

W A S WALSH E S GAULT and L MORRISON (*Amer J Digest Dis Nutrit* February 1938 p 789) report a rare case of primary carcinoma of the liver associated with *Clonorchis sinensis*. The liver fluke which is very common in the United States usually enters the human body as a result of eating fresh-water carp in a raw condition. In light infestations the symptoms may include dyspepsia epigastric and upper abdominal distress and

night blindness. When the disease becomes more advanced the liver descends below the right costal margin to a varying degree and recurring attacks of jaundice take place with chronic diarrhoea and vomiting. Anasarca finally appears and a severe cachexia sets in as a terminal stage of the disease. There is often a leucocytosis of over 20 000 white cells per cmm and an eosinophilia of over 40 per cent. If the intestation is severe small areas of liver necrosis 2 or 3 cm in diameter may be seen with marked cirrhosis—interlobular and around the ducts—causing obstruction of the portal circulation. Enlargement of the spleen chronic congestion of the gastro-intestinal tract and chronic gastro-enteritis may follow. In a few cases a primary carcinoma of the liver has been seen in association with the intestation. In one case reported a male Chinese aged 47 had suffered from vomiting pain in the upper right quadrant of the abdomen loss of weight and exhaustion for six weeks. The liver was enlarged and the abdomen distended. Biliary drainage revealed a marked duodenitis and catarrhal cholecystodochitis. Viable eggs of the *Clonorchis sinensis* were found in the bile. The patient test hospital but returned two months later and died within six days of an associated bronchopneumonia. Complete necropsy was refused but a stab biopsy of the liver showed marked interlobular cirrhosis areas of liver necrosis and a primary liver cell carcinoma.

## Surgery

### 436 Subtotal Gastrectomy for Duodenal Ulcer

H ANNES DIAS (*Arch Med Appar Dig* January 1938 p 31) after an extensive review of the literature comes to certain conclusions. Duodenal ulcer is cured spontaneously in 40 to 50 per cent of cases. It must not be considered as a local lesion but as an evidence of the mal function of organs other than the stomach and duodenum. Gastrectomy deals only with the local lesion and of the pathogenic factors corrects only the hyperchlorhydria and the gastritis. Cases of jejunal ulcer following gastrectomy are being reported in increasing numbers. The operation is a serious one with a high mortality except in the hands of highly specialized operators. It is a result in the disease agastria and may cause anaemia and disturbance of the intestinal functions and of the equilibrium with changes in the intestinal flora. It is a mutilating and a physiological operation indicated only very exceptional. The problem of duodenal ulcer has not been solved by this operation as certain authors have claimed.

### 437 Saphenous Vein Ligation

P J SARMA (*Surg Clin N Amer* February 1938 p 129) gives the end results of ambulatory ligation of the saphenous vein for the treatment of varicose veins in 1 000 cases. The number of ambulatory ligations of the saphenous vein undertaken has increased rapidly every year since 1927. There were many recurrences following obliterative treatment and the majority of these were seen in those cases in which there was insufficiency of the saphenous valves. The thrombus produced by the obliterating solution could not be removed and the pressure of the column of blood canalization of the thrombus resulted and in a short time the varicosity reappeared. The Trendelenburg test was carried out in order that the cases might be classified. A positive test signifies incompetence of the saphenous valve and the regurgitation of blood into the saphenous vein from the femoral. Ligation treatment followed by chemical obliteration is indicated in the

cases. Ligation is contraindicated by any systemic or degenerative disease. If an acute local or general infection is present ligation should be postponed until the patient is free from such conditions. Careful examination should be made to rule out any possibility of severe cardiac disease, arterial disease of the lower extremity, or thrombo-angitis obliterans, before treatment is undertaken. Ligation of the saphenous vein at the sapheno-femoral junction is the operation of choice. When the superficial circumflex iliac and superficial epigastriac veins or the external pudendal veins empty into the upper end of the saphenous instead of the femoral vein, they are also ligated. The technique of the operation is fully described. A 5 per cent solution of sodium morrhuate and a 5 per cent solution of mono-ethanolamine oleate have proved the most satisfactory obliterating solutions. Good results were seen in 958 of the 1,000 patients treated.

438

## Rubber Grafts

D FIESCHI (*Rev Chir* Paris, January, 1938, p 1) describes the results which have followed the use of rubber grafts in different types of operation. It was found that rubber sponge was well tolerated by the tissues, and that after a few days connective tissue invaded the holes of the rubber and incorporated it into the tissues. The various cases in which this method of treatment has been tried successfully include one of inguinal hernia with a large orifice and a tendency to recurrence, a large ventral hernia, and a femoral hernia. It has also been used for fixation of a mobile kidney, the formation of artificial breasts in comminuted fractures, and as a substitute for a testis which had been removed. In the case of herniae it has been possible for the patient to return to work without risk of recurrence, and illustrations are given showing the graft in position after as long as twenty-eight years. The procedure is as follows. The patient is placed in the Trendelenburg position, and after laparotomy the sac is exposed and opened. Digital exploration of the canal is then carried out, and the canal is filled with a pad of rubber, which is sutured at three points by fine catgut sutures. The abdomen is then closed. It has been found from experience that rubber is a most suitable material as it is easy to use and can be cut to any required size. It does not need any nutrition from the body, and has an elasticity equal to that of normal tissues, it is indestructible, and can be rendered completely sterile.

439

## Thoracoplasty

P DREYFUS-LE-FOYER, R ETIENNE, C BRUNET, and O RENIE (*Rev Tuberc* February, 1938, p 130) review the experiences of the Aincourt sanatorium, where most of the patients are in an advanced stage of tuberculosis. With an accommodation for 300 patients at a time, it dealt with 1,061 patients between January, 1935, and January, 1937. Only thirty-five of these patients (3.3 per cent of the total) were selected for thoracoplastic operations, and only three of them could be considered as fulfilling all the indications for such treatment; the remaining thirty-two were borderline cases in this sense, yet as many as twenty-five achieved recovery as judged by clinical, radiological, and bacteriological standards. Several of them have returned to their families without signs of relapse. The authors attribute this large measure of success primarily to the team work developed between the physicians and surgeons of the institution. The fresh air, rest, and discipline also did much to consolidate the success of the operations. For purposes of comparison the authors give the results of treatment in 1936 for all their patients: cured, 13.55 per cent; improved, 27.95 per cent; stationary, 30.78 per cent; worse, 21.45 per cent; and dead, 6.25 per cent. The authors had no operative deaths, although at least one of their patients among the thirty-five suffered from heart disease.

1192 B

## Therapeutics

440

## Neosalvarsan for Bronchopneumonia

B EBENIUS (*Klin Wschr* November 13, 1937, p 1611) describes the results of the administration of neosalvarsan for bronchopneumonia occurring in two patients with cancer of the hypopharynx and one with cancer of the tongue. In each case 0.3 mg of neosalvarsan was given intravenously. The injection was followed by a rigor within one and a half hours in all three patients. The temperature fell to normal in twenty-four hours in two and in six hours in one patient. A rise of temperature is noted in some susceptible people after the administration of salvarsan. Four further patients were then treated; three of them had cancer, one erysipelas, and bronchopneumonia was not present in any of them. No rigor or rise of temperature was noted. The author believes that a salvarsan reaction is specific in cases of bronchopneumonia and that it kills a large number of organisms the toxins of which produce the rigor. When the toxins are dealt with the temperature falls. Further experiments are being carried out to determine whether salvarsan is specifically bactericidal to certain strains of pneumococci and haemolytic streptococci.

441

## Grenz Rays for Alopecia Areata

E LAST and R O STEIN (*Arch Phys Ther* February 1938, p 99) have used Grenz rays (Bucky rays) in forty cases of alopecia areata, some ten of which were of the malignant type in which Grenz rays have no specific effect on the alopecia though they produce a profound hyperaemia. The success of the treatment depends on the use of the correct dose. Doses over 1,400 r units may under certain conditions cause temporary epilation, but no permanent injury to the hair papillae. The authors use 800 to 1,000 r units. The dose can be repeated, if necessary, twice, at intervals of ten to twelve weeks. The erythema caused by the irradiation appears in about the third week and persists for a long period. The regrowth of the hair starts at about the end of the sixth week. The method has proved successful in cases where all other forms of therapy have failed.

## Laryngology

## 442 Oestrogenic Hormones in Atrophic Rhinitis

H MORTIMER, R P WRIGHT, and J B COLLIP (*Canad med Ass J* November, 1937, p 445) studied the cranial skiagrams of sixty-eight cases of atrophic rhinitis and ozaena and found that a large majority showed changes in the bones of the skull and face which indicated a dyspituitary state during or subsequent to the growth period. "Dyspituitarism" denotes an instability of function of the pituitary gland which tends at times to hypofunction, at other times to hyperfunction. In this condition the cranial bones have an abnormal mode of growth, especially in certain areas—for example, the well-recognized pathological changes in the lateral wall of the nose in atrophic rhinitis. But the changes in the mucous membrane of the nose cannot be explained by the pituitary factor, and the authors believe that the sex hormones play a part here. In the monkey crystalline female sex hormone produced changes in the nasal mucosa of an order opposed to those found in atrophic rhinitis. As a local treatment of the nose with dihydroxy oestrin was therefore tried in the authors' cases of ozaena. After removing all the crusts from the nasal cavity the oestrin is applied in the form of an oily spray. In milder cases the patient merely uses an alkaline spray before the oestrin spray. The improvement which resulted was more marked in the females than in the males, but there is no doubt

that the oestrin also had a beneficial effect on the middle conchal mucosa. It is claimed that oestrogenic hormone insufflation constitutes a mode of treatment for ozena and atrophic rhinitis considerably more effective than any other as yet available.

#### 443 Aural Vertigo

A. J. WRIGHT (*J. Laryng.* February 1938 p. 97) analyses seventy-three cases of aural vertigo from a clinical point of view. In all the patients except two some loss of hearing existed in the affected ear; in these two a history of temporary deafness during the attacks was obtained. In more than half the cases the first symptom was auditory and not vertiginous. In the former group deafness was the initial symptom in one third and tinnitus in the remaining two thirds. Patients with active middle ear suppuration were excluded from this review. The tympanic membrane on the affected side was normal in fifty-two cases. There was some degree of opacity in five and more or less extensive post-suppurative cicatricial changes in nine cases. The Eustachian tubes showed no pathological change in nine cases contrary to the view held by other observers. One or more foci of infection were noted in all cases; these foci consisted of infected teeth, tonsils, antra, gall bladder or uterus. Twenty-three cases in this series were treated surgically by the eradication of one or more septic foci and all were cured of the vertigo. The author concludes that the condition is a definite clinical entity which he calls "local labyrinthitis" and he defines it as a chronic progressive lesion of the labyrinth running a very irregular but long course and always producing some permanent damage as evidenced by loss of hearing. (See also *Journal* March 26 p. 668.)

#### 444 Effect of Tympanic Lesions on Hearing Acuity

J. E. BORLEY and M. HARDY'S experiments (*Arch. Otolaryng.* December, 1937 p. 649) are based on the assumption that cochlear potentials vary with changes in the intensity of the sound that reaches the cochlea. A cat's middle ear was exposed by removal of the bulla without injuring the tympanic membrane. The cochlear potentials are picked up by two electrodes, one the tip of a silver wire placed on the cochlea near the round window, the other a thin flat bar of silver placed in the sterno-mastoid muscle. These electrical potentials are passed through a suitable amplifier to an earphone in another room. If a normal person's hearing is then tested by a pure tone audiometer containing the leads from the cat's cochlea in the circuit the audiogram obtained indirectly represents the hearing power of the animal's ear. Under such test conditions the authors made incisions in the various quadrants of the cat's tympanic membrane and tested the hearing after these injuries. Incisions in some quadrants of the drum membrane produced a greater interference in the hearing than incisions in other quadrants. When a small piece of tracing paper soaked in liquid paraffin was used to repair the lesion a definite improvement in the transmission of sound occurred. Audiograms of patients with traumatic rupture of the tympanic membrane closely resemble those obtained from the cat's ear. This experimental evidence supports the view that changes in cochlear potential actually do parallel changes in hearing acuity.

#### 445 Double Abductor Paralysis

E. LUSCHER (*Schweiz. med. Wschr.* February 26 1938 p. 199) describes two cases of double abductor paralysis, a rare condition in which an operation originally introduced by Wittmaack was performed with very satisfactory results. When a patient suffers from double abductor paralysis he usually has to have a permanent tracheotomy. Various operations have been tried with the object of widening the aperture of the glottis so as to render the

tracheotomy unnecessary. Such operations aimed at a lateral displacement of one or both vocal cords and seriously interfered with the voice. Wittmaack introduced a new surgical principle because his operation effected a downward displacement of one cord and the other one then passes sideways between the normal cord and the one which has been displaced downwards. This results produced by the resection of the muscular process of arytenoid cartilage. The arytenoid cartilage with the attached vocal cord falls forwards and downwards and the level of the cord on the operated side rises to a distance of about 5 mm. Stenosis is relieved, the tracheotomy can be allowed to close and phonation remains surprisingly good.

#### 446 Otitis Media and Vitamin C

M. BAER (*Rev. Laryng.* February 1938 p. 165) attempts to establish a relation between poor states of nutrition due to anence or deficiency of certain vitamins and the development of otitis media. Twenty-six cases of acute middle ear suppuration were investigated, including suppuration in children, sifter connected with dental and gastrointestinal disturbances. In addition to these other predisposing factors such as racial predisposition, influenza infections. In order to concentrate on the vitamin factor cases with obvious predisposing factors were eliminated. In the remaining thirteen cases analysis of the urinary output of vitamin C gave figures which invariably indicated a deficiency. Treatment by administration of ascorbic acid was only started when the otitis had reached a condition at which it was unlikely to respond in any way to local treatment. In all the thirteen cases it was clearly demonstrated that the administration of vitamin C had a most beneficial effect in resolving the middle ear suppuration.

### Obstetrics and Gynaecology

#### 447 Hyperemesis Gravidarum

E. KEHRER (*Z. Geburtsh. Gynäk.* 1938 116 3 353) distinguishes between psychogenic hyperemesis occurring in those with hyperexcitability of the vegetative nervous system but not necessarily with neuropathic or hysterical attributes and the more severe toxic form which may be pernicious from the first or may be superimposed on the psychogenic form. After a detailed review of the pathology in which he stresses the importance of chloride loss and hypochloreaemia and of disturbance of glycogen from excessive vomiting and from hypersecretion of some of the anterior pituitary hormones he defines three successive stages in hyperemesis. In the first an unexplained primary component in the central nervous system causes exaggeration of physiological vomiting. The second component psychogenic in origin causes (1) vagotonia and hyperexcitability of the vomiting centre and (2) partial hyperpituitarism with hypersecretion of the gonadotropic hormones and those stimulating thyroid secretion and fat and carbohydrate metabolism. In the third stage characterized by disturbed metabolism, toxemia and hepatopathy there is a severe auto-intoxication due to the presence in excess of normal or abnormal metabolic products, there is loss of water, chlorides, carbohydrates, proteins and vitamins followed finally by degeneration of the liver. In an exhaustive discussion Kehrer deprecates local gynaecological treatment, advocates derivatives of bromine or luminal as sedatives and emphasizes the importance of psychotherapy. Admission to hospital eliminates disturbances from outside as well as from family influences. The rectal or parenteral exhibition of normal saline solutions is recommended or the intravenous administration of 10 ccm of 5 per cent saline (10 to 20 per cent) twice daily when hypochloreaemia is found. The combination of such treatment with glucose is found.

insulin therapy is often of value. Hypocalcaemia calls for the administration of calcium, preferably by intramuscular injection. Alkalis given in large amounts or intravenously may be dangerous, for alkalosis, not acidosis, is present in some cases. Suprarenal cortical extracts and vitamins C and/or B, have proved effective in some cases. Kehrer is less convinced of the efficacy of follicular, luteal, or male sex hormones, or of feeding through the duodenal tube, induction of labour is very rarely justified. Kehrer has abandoned his former opinion that the decision as to induction should be based on clinical findings rather than on biochemical investigations, and now thinks that these should be studied jointly and equally, oliguria is less important than in the nephropathies of pregnancy, ketonaemia is more important than ketonuria, increased bilirubinaemia than increase of urinary urobilinogen.

## 448

## Local Analgesia

R. TACHEZY (*Schmerz Narkose-anaesth* February, 1938, p. 185) discusses pain referred from viscera, and describes Head's zones of cutaneous hyperaesthesia, which are as follows in painful gynaecological conditions: in inflammation of the adnexa, an elongated area over the middle part of Poupart's ligament, the pain radiating outwards and down the lower limb; in extra-uterine gestation the pain is at the same spot, but radiates to the ribs and shoulder; uterine pain is felt above the pubes, cervical pain lower down in the same area and in the lumbosacral region. These localizations are useful not only in diagnosis but also in the treatment of severe and intractable pain which cannot be radically or quickly cured. The treatment consists of local infiltration of the subcutaneous tissues over a wide area in the painful region, usually one injection gives immediate relief, lasting eight to ten days, after which it may be repeated. Three injections have usually given lasting relief from pain. The author uses 0.5 per cent novocain. Of fifty-five cases he reports, thirty-six gave very good results, seventeen moderate results, and two were failures.

## 449 Liver Therapy in Hyperemesis Gravidarum

E. MUHLE (*Zbl. Gynak.*, March 19, 1938, p. 645) describes a case of hyperemesis gravidarum in the second month of the pregnancy in which he injected liver extract to counteract a severe anaemia. All the usual therapeutic methods had failed to give relief, but this was obtained after the first injection. In the past year he has treated in this way twenty cases, of which ten were severe, with only one failure. Only two patients required hospitalization. In all cases a diet poor in proteins and fats and rich in carbohydrates but with no-milk was prescribed. Rest in bed was advised where practicable, but not enforced. Intramuscular injections of liver extract were administered daily in severe cases, on alternate days in mild ones, until all the symptoms had disappeared. The author does not know of any contraindications to this treatment. There is no explanation of this favourable action of liver extract. The doses are too small to account for its rapid action, which is in a sense similar to that of liver in the treatment of bismuth and lead poisoning.

## 450 Alcohol Injection for Pruritus Vulvae

W. M. WILSON (*J. Amer. med. Ass.* February 12, 1938, p. 493) was prompted by the successful results of Stone's treatment of anal pruritus by alcohol injection to try it in pruritus vulvae; he now reports his results in forty-nine cases (of an average duration of eight years), in most of which more conservative measures had been ineffective and in none of which could a causal factor be found. At one sitting and preferably under general anaesthesia from 2 to 4 minims of 95 per cent alcohol were injected just beneath the dermis at each of a number of

points at least 1.5 cm apart, the amounts injected were kept low in elderly or arteriosclerotic patients or in those with vulval or anal varicosities. Oedema, thickening, and itching disappeared almost at once, and the improvement outlasted the return of normal vulval sensation three weeks later. Twenty-four patients had enduring relief from one injection, but in thirteen the injections were repeated, being lastingly successful in two, in only two patients was this treatment completely ineffective. In two patients incision was necessary for haematomata or necrosis. The effect of the alcohol is due first to degenerative changes in the cutaneous nerve fibres, second, and probably more important, is the rapid mobilization in the chronically inflamed subepidermal zone of polymorphonuclear leucocytes and of histiocytes from the reticulo-endothelial system.

## Pathology

## 451 Hormonal Control of Vas Deferens and Vesiculae

T. MARTINS, J. R. DO VALLE and A. PORTO (*Brazil med.* February 26, 1938, p. 225) have made a study of the vas deferens and seminal vesicles of rats, amounting in all to 140 organs. In Locke's solution *in vitro* the vas deferens and seminal vesicles of castrated animals showed spontaneous contractions, and were insensitive to stimulant drugs in general, and especially to parasympatheticotonics. The vas deferens of normal rats did not show any automatism. There were also qualitative differences regarding the type of reaction, the reaction of normal organs had always a tonic character, while the organs of castrated rats showed only rhythmical contractions with little or no tonic character. In the vas deferens of castrated rats which had been treated with oestradiol benzoate the castrate type of motility *in vitro* was exaggerated. Injection of the castrated rats with testosterone or testosterone propionate produced the normal type of reaction. Injection of progesterone in the doses given (a total of 5 to 18 mg in the course of ten to twenty days) failed to have any inhibitory reaction. The writers conclude that the motility of the vas deferens and vesiculae seminales is normally under hormonal control and the testicular and oestrogenic hormones have different actions, the former inhibitory and the latter stimulating.

## 452

## Thrombopenia

L. BLACHER (*Sang.* 1938, 12, 1, 26) discusses the pathology of Werthol's essential thrombopenia, and gives the results of his observations on four cases. (1) The bone marrow in congenital thrombopenia produces a sufficient number of platelets. (2) The state of the platelets in the splenic artery, vein, and parenchyma shows that in this disease the spleen is apparently endowed with an exaggerated capacity for retaining and breaking down blood platelets. Characteristic bodies known as "laminated splenic bodies" have been found in the parenchyma of the spleen and at times in the peripheral blood, these are taken to be a manifestation of splenic hyperfunction. (3) In congenital thrombopenia the "thrombodiagrams" of the peripheral blood are similar to those of the bone marrow. (4) The number of platelets per cmm of peripheral blood, even after injections of adrenaline, is in no way related to the experimental bleeding time; on the other hand, there is a definite relation between the bleeding time and the thrombocyte index, the quality of the platelets and the pathological activity of the liver. (5) Marked thrombopenia occurs in functional disturbances of the endocrine glands, particularly of the gonads. (6) In the four cases observed the thrombopenia remained stationary while the "haemorrhagic diathesis" appeared or disappeared in accordance with the periodic activity of the gonads. The author concludes by suggesting that this disease should in future be known as "dysfunctio-haemorrhagica hepato-lympho-toxicogenica."

## Pure, active, comfortable and inexpensive

An increasing tendency is shown to claim a very high purity and remarkable haemopoietic potency for injectable fractions of liver

Independent chemical research in stringent conditions of clinical test have maintained a place for Organon's PERNAEMON FORTE in this field

PERNAEMON FORTE, now a clear solution provides a medium for the therapy of Pernicious Anaemia as pure as active as comfortable and as inexpensive as any available.

**BETTER CLINICALLY  
AND A BETTER INVESTMENT**

No need to discuss with you the advantages of having an electrocardiogram of every patient whose heart is suspect. You know how accurate tracings made by the heart itself point the way to better earlier diagnosis and to more accurate prognosis.

You know too that ownership of a dependable accurate electrocardiograph would be a worth while investment if such a precision instrument were purchased at a fair price and on reasonable terms. There is such an instrument—an entirely new product. It is the Victor Portable Electrocardiograph lower in price but better in every way better from the viewpoint of both physician and patient. Certainly it merits your consideration.

Won't you post the coupon today? You will learn from an unusually interesting booklet which we will send what a good electrocardiograph this is and how much it would mean to you to own it.

**SIMPLE**

You can learn to use it in half an hour

**CORRECT DESIGN**

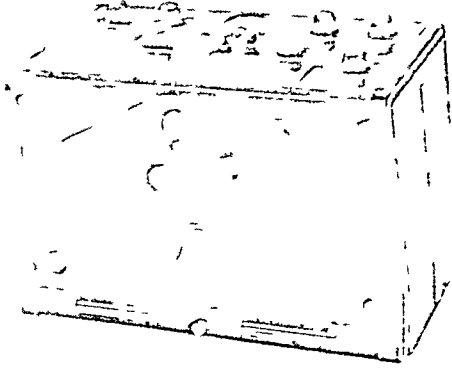

Extremely accurate highly sensitive consistently uniform

**PORTABLE**

Weights only 42 pounds self contained power supply

**LOW-PRICED**

Well within the purchasing power of all physicians

# ST. ANDREW'S HOSPITAL FOR MENTAL DISORDERS NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY

President THE MOST HON THE MARQUESS OF EXETER CMG ADC

Medical Superintendent THOMAS TILNENT MD MRCP DPH DIM

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients who are suffering from incipient mental disorders or wish to prevent recurrent attacks of mental trouble temporary patients and certified patients of both sexes are received for treatment. Careful clinical biochemical bacteriological and pathological examinations. Private rooms with special nurses male or female in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

## WANTAGE HOUSE

This is a Reception Hospital in detached grounds with a separate entrance to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods including Turkish and Russian baths the prolonged immersion bath Vichy Douche Scotch Douche Electrical bath Plombieres treatment etc. There is an Operating Theatre a Dental Surgery an X-ray room an Ultra Violet Apparatus and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical bacteriological and pathological research.

## MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk meat fruit and vegetables are supplied to the Hospital from the farm gardens and orchards of Moulton Park. Occupation therapy is a feature of this branch and patients are given every facility for occupying themselves in farming gardening and fruit growing.

## BRYN-Y-NEUADD HALL

The seaside house of St. Andrew's Hospital is beautifully situated in a park of 330 acres Llanfurfach amidst the finest scenery in North Wales. On the North West side of the Estate a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout fishing in the park.

At all the branches of the Hospital there are cricket grounds football and hockey grounds lawn tennis courts (grass and hard courts) croquet grounds golf courses and bowling greens. Ladies and gentlemen have their own gardens and facilities are provided for handicrafts such as carpentry etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton) who can be seen in London by appointment.

# THE EXAMINING BOARD IN ENGLAND

BY THE  
ROYAL COLLEGE OF PHYSICIANS OF LONDON  
AND THE  
ROYAL COLLEGE OF SURGEONS OF ENGLAND

## DIPLOMA IN ANAESTHETICS (D.A., R.C.P. & S.Eng.)

The following clause in the regulations for the Diploma in Anaesthetics has now been withdrawn —

*Until May 1st 1938, it shall be open to the Royal Colleges on the recommendation of the Committee of Management of the Examining Board to grant the Diploma without examination to an Anaesthetist to a general hospital associated with a recognised medical school in the British Empire who has held this appointment for not less than ten years*

The Committee of Management has now been authorised by the Royal Colleges to consider applications up to December 31st 1938 for the award of the Diploma without examination from Anaesthetists who while not strictly eligible under the previous

conditions approach them so nearly as to give them in the opinion of the Committee the necessary experience and standing in the profession to justify their names being submitted to the Royal Colleges for the award of the Diploma

Enquiries should be addressed to the Secretary of the Board,  
8 11, Queen Square London, W.C. 1

# HERMAN'S PRACTICE of UROLOGY

**JUST OFF PRESS!**

**A Practical Book**  
*by*

**LEON HERMAN, B.S., M.D.**

Professor of Urology University of Penn  
sylvania Graduate School of Medicine Octavo  
of 923 pages with 736 illustrations on 204  
figures Cloth 42s ret.

Dr Herman's new book is truly To-day's Practice of Urology. It brings to everyone concerned with urological disease a clear, concise and specific presentation devoted to the practical everyday methods of diagnosis and treatment.

But it is the Family Physician who will especially appreciate and welcome this work. Dr. Herman has taken into account those factors that enter into the treatment of urological disease as it is most commonly met in general practice. He describes each method of examination, how to apply it, and what it means. He contrasts normal with abnormal, gives you tests such as the Menthin test, McLern urea concentration test, phenolsulphonphthalein test, etc., and their clinical interpretation. He gives you methods of treatment that you can institute at once in your own practice. Systemic and dietetic measures, with actual prescriptions and menus. Diuretic treatment, use of anti-epileptic, solutions, drugs, etc., and indications for surgical interference are given in full detail.

There is an especially fine discussion of Gonorrhoea in the male covering six chapters in which Dr Herman omits no detail or practical importance and assistance. The use of sulphamamide, diathermy, repressive treatment, hind injection irrigation vaccine intraprostatic injection, and other methods are described in the light of Dr Herman's own clinical experience.

Five unusually complete chapters are devoted to the Prostate Gland and there is a full consideration of venereal ulcers including the treatment of chancroid.

For sound, practical and authoritative guidance in to-day's methods of clinical diagnosis and treatment we believe this entirely new book is unsurpassed.

THE LANCET 335

[illegible][illegible]

*Dr Herman's work is thus exactly what he intends it to be—A practical treatise of diseases of the urogenital system for the use of general practitioners and surgeons.*

# For HEALTH'S SAKE—an ELECTRIC REFRIGERATOR

Your training makes you alive to the danger of contaminated food. But few outside the medical profession realise how important it is to family health that food should be kept always below the 50° F danger point—above which germs tend to multiply very rapidly. Imported meat comes to us in ships' holds scientifically kept at the safe temperature, and our milk is just as carefully safeguarded before we buy it. Yet in too many homes these precautions are neglected from the moment the food is bought from the shop. You are in a position to educate the public upon this important subject. And remember, an electric refrigerator can be relied upon to keep food below the 50° F mark, even in the warmest weather—and an electric refrigerator is within the reach of most families in these days—to purchase it costs not more than one penny per day per person in the average household.

For useful information on Electric Refrigeration send for the special booklet to the British Electrical Development Association 2 Savoy Hill London W.C.2, or consult your local Electricity Authority.

'Here's  
another

'An O.D.B. has the A.B.C.  
of health!'

HOT BATHS  
FOR ALL  
EVERY DAY!

The Order of the Daily Bath

There's the A.B.C. of health! And why  
deserve it? If you take a clean skin  
through the pores of your skin, you  
will be sure to have a healthy skin.  
That the skin always functioning itself  
and must be kept clean, the condition of  
personal cleanliness and for real health.  
SOAP & HOT WATER, I TELL YOU.  
Not only wash—but rub. rub  
Leave the skin to dry naturally, and  
body for more than 12 hours, and  
becomes soft, supple, and supple.  
The skin cannot breathe properly con-

not do good work. Keep these pores  
clean! Give them their daily bath!  
GAS IS YOUR WARMEST FRIEND  
Thank you, Gas has solved the hot water  
problem — for good! The real Gas  
heaters are clean, economical and  
unusually durable. If your present  
hot water system prevents you from  
having all the bath you need, go and  
ask someone at your Gas Department.

For FRESH HEALTH  
Join Mr. Therm's

ORDER of the DAILY BATH

of my O.D.B. advertisements'

says Mr. Therm

It's a bit small for you to read in  
this reduced form. But you prob-  
ably have seen it and others of the  
same series full-size in the daily  
press.

Mr. Therm's initials O.D.B. stand  
for the Order of the Daily Bath.  
In a restrained way Mr. Therm  
is advocating a daily bath for all.

He is arguing along health lines,  
and he hopes he has the support  
of medical opinion. He is saying  
that a daily bath keeps the skin  
clean and obviates some of the  
disorders of the body.  
Mr. Therm would be delighted to  
know he had doctors behind him  
in principle.

**O.D.B. is the ORDER of the DAILY BATH**

*the slogan used in a series of national press advertisements*

# DESOUTTER

## CASE RECORDS

### Case No H2354/1673 1936

The patient was suffering from muscular hypertrophy of the right leg, the circumference of the calf being twice, and the ankle nearly three times, that of the sound limb. The foot was deformed, necessitating a special shoe and the patient's walk was most ungainly (Fig 1).

At the request of the surgeon, Mr. Desoutter examined the patient in hospital before amputation to give his opinion as to —

1. *The best site of an amputation in view of the peculiar difficulties of the case*
2. *The prognosis from the point of view of appearance and ability to walk well with an artificial limb*

It was decided to amputate 7" below the knee joint and to remove the hypertrophied nodule on the inner side of the leg. Figure 2 shows the great success with which the operation was performed. The scar on the inner side of the leg extending from the end of the stump to just under the knee seemed at first to need special attention but by very careful

fitting of the artificial limb serious trouble was avoided. Careful physical re-education played a large part in the success of this case and the patient now walks very well and has a natural appearance.

*A little  
booklet*

*with a big  
purpose*

Crêpe  
Bandages  
for  
Medical  
Practice

This booklet contains valuable information concerning the many useful functions of the crepe bandage in every day cases. Written by an eminent medical authority it is a handbook well worth possessing. The Norvic crepe bandage, known and recommended for its remarkable elasticity which is arrived at by a special weaving process does not contain rubber in any form. It is given special mention in this interesting booklet. POST FREE on application to—

# Spencer Individually Designed Bandeaux

## PROVIDE UPLIFT WITHOUT CONSTRICTION

Spencer Bandeaux designed individually for each wearer provide specific and continuous uplift for even the heaviest breasts.

The bust pockets are made of a slightly stretchy soft material that permits of free breathing without constriction.

The below bust section of a Spencer Individually Designed Bandeau is fashioned of non-stretchy fabric designed shaped and made to fit snugly preventing the breasts from sliding out of the bust pockets.

The back section is designed to stay firm and attached to the figure so that the weight of the breast cannot pull the back of the bandeau upward on the figure and lessen the degree of uplift that is desired.

Doctors prescribe Spencer Bandeaux for the following reasons:

- 1 To prevent sagging of the muscles and skin and subsequent ptosis
- 2 During pregnancy and for nursing mothers to provide support and uplift without pressure on the nipples
- 3 As a preventive of breast abscesses and caking

Spencer Bandeaux are prescribed by thousands of doctors for their wives and nurses as a general health measure.

An excellent example of a Spencer Bandeau

**BEWARE OF SUBSTITUTION**—Spencer Corsets Ltd. regret the necessity of warning the medical profession that in several instances where doctors have specifically prescribed a Spencer Support or corset of another make has been substituted and because its makers do not understand the Spencer principles of individual designing has been unsatisfactory. Every genuine Spencer Support bears the SPENCER Label.

Trained Spencer Corsetters are resident throughout the Kingdom. Name or near it, gladly supplied on request.

As clients, all trained Spencer Corsetters will advise you on the best support for your figure and to take your measurements.

# AMPLIVOX HOUSE

## The New Home of the HIGH FIDELITY HEARING AID

Amplivox House accommodates an organization which in three years has become the world's largest manufacturer of High Fidelity Hearing Aids. This success has been achieved solely through the recommendations of medical men and enthusiastic users. Here is definite proof that sufferers from deafness are now fully alive to the vital importance of using high grade instruments and are putting performance first in purchasing a hearing aid. At Amplivox House they can compare all types of hearing aids with the many Amplivox models. They can avail themselves of the unique facilities offered by an organization which concentrates all its energies on the production of hearing aids for use individually and in churches, schools, theatres etc., and the development of special acoustic apparatus for the medical profession. Details of the full range of Amplivox aids should be in the hands of every Medical Practitioner.

## Efficient and Effective Support

### SCIENTIFICALLY Applied

The secret of the success of the Curtis Abdominal Support No. 1 lies in its scientific application of power. At all times it gives even anterior posterior pressure without undue constriction of the lower abdomen. The resulting support obtained allows for greater freedom and comfort than ever before. Medical men prescribe the Curtis Model No. 1 for all forms of abdominal ptosis—visceroposis, enteroptosis and gastropptosis, and it is also recommended for support of ventral hernia and scar tissue in the lower abdomen.

## EXTRA-CELLULAR NUTRIMENT FOR MORE COMPLETE ASSIMILATION IN INFANT DIETARY

By the Libby process of Homogenization the tough walls of food cells are burst and broken up into fine particles. The nutriment thus being extra-cellular is therefore rendered immediately accessible to the gastric enzymes and thoroughly assimilable without digestive strain.

FIG 1

The break up of the fibrous tissue has the added advantage of providing smooth non irritating bulk and obviating the incidence of intestinal disorders—particularly

diarrhoea—primarily due to the passing of food cells through the digestive tract with their tough outer walls intact.

FIG 2

Photographs show the comparative difference in stools after feeding with (Fig 1) Libby's Homogenized vegetable, (Fig 2) commercially strained vegetable and (Fig 3) home strained vegetable.

Libby's Homogenized Vegetable Foods are eminently suitable for very young and weak digestions and can be prescribed with confidence in very early cases of nutritional anaemia. They are prepared in six scientifically formulated combinations of Cereal Vegetables and Fruit. These can be prescribed as needed to provide the necessary balance of Vitamins, Minerals and other essentials.

FIG 3

Samples to either with clinical data and laboratory reports will be gladly supplied upon request to Messrs Libby McNeill & Libby Ltd, 15, Lime Street, London, E.C.3.

## Appointments for Medical Officers in The ROYAL AIR FORCE

Medical men are invited to apply for Short Service Commissions in the Royal Air Force.

Candidates must be registered under the Medical Acts and be not more than 35 years of age on entry.

The period of service is 3 years—extendable to 5 years. A gratuity of £400 or £1,000 is payable at the termination of 3 or 5 years respectively. Permanent commissions are awarded in a number of cases. These offer a pensionable career with the opportunity of extra leave on full pay for specialised study.

Applicants who hold—or are likely to hold—post-graduate appointments in civil hospitals may, on joining the Royal Air Force, be recorded until the termination of their appointments (for a period not exceeding one year). An antedate of commission, up to twelve months is allowed for appointments held at approved hospitals.

For further information, or to obtain forms, apply to The Director of Medical Services, Air Ministry, Kingsway, London.

# <sup>6</sup>A.B.<sup>9</sup> Protamine BRAND Insulin (WITH ZINC) S U S P E N S I O N

The absorption of insulin injected in the form of 'A B' Brand Protamine Insulin (with Zinc) Suspension is much prolonged and closely resembles the natural secretion of the pancreatic islets. This insulin has a steady action and exerts a better control than that of ordinary insulin over the carbohydrate metabolism. The number of injections can be reduced and lower total dosage is usually necessary, and the subjective symptoms of diabetes markedly improve.

40 units per c.c.	80 units per c.c.
5 c.c. (200 units) 2/4	5 c.c. (400 units) 4/6
10 c.c. (400 units) 4/6	

INSULIN 'A B' was the first British insulin offered commercially to the medical profession, and has a world-wide reputation for its strictly safeguarded sterility, its carefully standardised strength, its freedom from toxic reactions and its stability in hot climates.

Full particulars will be sent free to members of the Medical Profession.

## INFANTILE ECZEMA RAPIDLY ALLEVIATED \*

As a medical man you will agree that one of the principal difficulties in treating cases of eczema in children is the interference by the patient provoked by the intense irritation. Successful local treatment therefore calls for a soothing dressing. It is this property of Sphaonol Peat Ointment which makes it so valuable. The peat distillate which it contains soothe from

the first application. At the same time, these healing anti-peat distillates assist in the growth of normal skin. In case you have had no personal experience of Sphaonol we shall be pleased to send you a clinical size sample free of charge if you will write to Peat Products (Sphaonol) Ltd., Dept. B.M.J. 21 Bush Lane London E.C.7.

## VITAMIN B<sub>1</sub> B.D.H.

The importance of Vitamin B<sub>1</sub> in metabolic processes is being increasingly realised. At the same time, clinical experience is confirming that the usual dietary is deficient in this important substance. Such minor deficiencies as are commonly met with can be adjusted by the administration of Vitamin B<sub>1</sub> as included in Multivite.

There are, however, certain pathological conditions of fairly high incidence which indicate a more serious deficiency of Vitamin B<sub>1</sub> and require treatment with the pure vitamin in considerably larger doses

than are practicable through the medium of Multivite.

For the treatment of these more serious deficiencies, symptoms of which may include constipation, anorexia, bradycardia and neuritis, Vitamin B<sub>1</sub> B.D.H. is available in the form of solutions—2 mg (1000 international units) per c.c. and 10 mg (5000 international units) per c.c.—for parenteral administration and in the form of tablets—1 mg (500 international units) per tablet—for oral administration.

Samples of any of the above will be sent on request.

# MANDECAL

(Calcium and Calcium Mandelate) BDH

The outstanding advantage of Mandecal in the treatment of urinary infections lies in the fact that it is palatable and causes no gastric discomfort as is sometimes experienced by patients taking other forms of mandelic acid. Further, the characteristic immiscibility of calcium mandelate has been overcome in Mandecal, which is a fine powder mixing readily in water to form a suspension easily taken in a draught. Finally, in Mandecal therapy the collateral administration of ammonium chloride is usually unnecessary, the pH of the urine being maintained at the correct level by the action of Mandecal alone.

## *The respective merits of* **DETOXICATED and TOXIC VACCINES**

The obvious advantage of Detoxicated Vaccines is that large doses can be administered without causing serious reactions. This is of great value in the treatment of cases where any given bacterial disease is already established. In such cases toxic vaccines are apt only to aggravate the symptoms whereas moderate doses of the appropriate detoxicated vaccine can be given safely without further aggravation of the disease.

We have always upheld the superiority of detoxicated vaccines but some authorities prefer the toxic varieties because they believe that it is important to obtain more or less marked reactions in order to produce a satisfactory immunity.

The toxic vaccines have the advantage of cheapness. The detoxicated vaccines are more expensive for the obvious reason that the dosage is nearly one hundred times greater, so that much larger quantities of bacteria are used in their preparation.

We supply both the detoxicated and the toxic varieties of vaccines in order to cater for the two different schools of thought in this matter. A booklet, giving details of our full range of Detoxicated and Ordinary Vaccines, will gladly be supplied on request.

Intestinal glands	003 grm
Biliary extract	010 "
Lacue ferments	- 00,
Agar agar	- 00,
Fiat tablet - -	- 0 ,

Initial Daily Dose  
Two Tablets

*Laxatives*, it is well known now adds must have two essential characteristics

1 I find no biological reason the must  
accord with and immune in force on the  
natural population of the  
2 They must be capable of capturing the  
the one that has a more  
and the rate of capture is constant  
when the adjustment is made

Taxol in bottle and cruet

*Zaxol* has no effect on the central nervous system and no depressing effect on the respiratory system, but it does depress the heart which results in a low pulse rate. The relaxation of the heart is an important part of the correction of the heart and the restoring the circulation which has diminished in circulation. The stimulating action is gentle and does not cause the weakened tissue or efforts to build it power which would culminate in aggravation of the condition.

*Taxol* does not habit forming. It reduces the intestine to reumption of normal function unaided, thanks to the biological nature of its action. It contains no narcotic drug of violent and brutal action to which the measure can become accustomed. On the contrary, many stubborn cases of constipation after a course of *TAXOL* exert a tonic and regular peristalsis.

# THE MEDICAL CASE FOR A WHOLE WHEAT CRISPBREAD

**W**HEAT has always been Man's first choice among the cereals, whenever climatic conditions did not prevent his getting it. That remains true of all bread, either white or wholemeal, either soft or biscuit-crisp. And Vita-Weat, the wheaten crispbread with the **WHOLE** of the wheat left in it, has advantages which entitle it to a very high place among the staple foods of the world.

## ITS CALORIFIC VALUE

Bread is the 'energy component' and Vita-Weat, since it contains only 3 per cent. of water, has a fuel value nearly twice that of ordinary bread—according to *The Practitioner* its caloric value is 2,132 per lb.

Each section of such a crisp bread—each slice, so to speak—has a caloric value of 37. That is to say that in meeting what is probably the greatest requirement of a national staple food Vita-Weat is almost twice as effective as the other kinds of wheaten bread.

## STARCH AND DIGESTION

A crisp bread, obviously, calls for a more thorough chewing than a soft 'crumb' bread and mastication is therefore more healthily promoted. The starches and cellulose in Vita-Weat are also 'converted' into a more digestible form by the special processes which go to make a good crisp bread—just as toast and croutons have become greatly more digestible than bread is in its quite unconverted starch form. When the whole wheat berry is used the bran and fibre are thoroughly disintegrated.

The result is therefore, that the weight which guarantees a 'converted' starch places on the

digestion is almost entirely eliminated where Vita-Weat has been prescribed.

## VITA-WEAT AND ITS ADVANTAGES

In addition to these great advantages of superior fuel-value and digestibility Vita-Weat retains the 'protective' elements of the wheat-berry which are frequently rejected in the 'refining' of white flours. Proteins, vitamins and minerals in which bread is normally deficient are present and the 'balance' of this crispbread as a food is therefore increased.

The use of Vita-Weat can be shown to be especially desirable in cases of mild anaemia, liability to infection, lack of appetite, poor digestion, diabetes, obesity and as a food of 'protective' value to the teeth.

*A little booklet has been prepared for the medical profession briefly summarising the medical case for a whole wheat crispbread and it will gladly be sent post-free to any doctor on application to Peek Frean & Co., Ltd., Keetons Road, London, S E 16.*

# "HERE'S MY RECOMMENDATION"

says OLD HETHERS

The best barley water is that made freshly from Robinson's 'Patent' Barley. But an equally good and more convenient alternative is Robinson's Barley Water ready prepared for use and sold by the bottle. Made from Robinson's 'Patent' Barley it is available in a choice of two popular flavours—lemon or lime.

## ROBINSON'S BARLEY WATER

KEEN, ROBINSON & CO, LTD, Carrow Works, Norwich

# CRUNCHY FOODS AND THE DIGESTION

---

It is generally recognised by dieticians that hard foods are more easily digested than soft ones. The explanation commonly advanced is that soft foods are often swallowed in insufficiently chewed masses, whereas hard foods cannot be swallowed until they are properly broken up by the teeth, and in consequence the digestive juices have a larger surface area to work upon and their action is more effective.

Many physicians therefore recommend that the normal diet should contain a fair proportion of hard, dry food. They find that Ryvita, eaten regularly with meals, supplies a valuable factor in which the modern diet is otherwise deficient. Free samples of Ryvita for distribution to patients will gladly be supplied on request.

Metaphen is a powerful antiseptic  
It is the most effective disinfectant

## 250 TO 1,500 TIMES MORE GERMICIDAL THAN PHENOL

*depending upon the organism used in the test*

Amongst the numerous advantages of Metaphen (Abbott) the powerful antiseptic properties of the drug are of course the most important. In tests made under properly controlled conditions Metaphen has been shown to have a phenol coefficient of 250 to 1,500 depending upon the organism tested. Metaphen is relatively non-toxic to human tissue, is not painful on application, does not cause irritation or dermatitis, and does not precipitate in the presence of serum. Solutions of the drug

are stable when exposed to air. Metaphen is recommended in infections of the genito-urinary tract, eye, ear, nose, throat and skin. It is of value as a general antiseptic in surgery and for the disinfection of equipment. Metaphen is supplied through pharmacists in a variety of useful forms, the most widely employed of which are: Tincture Metaphen, a tinted alcohol acetone-queous solution prepared especially for use as a pre-operative skin disinfectant and for all other uses for which a power-

ful but sterile antiseptic tincture is indicated. Metaphen Solution 1:10, an aqueous solution which is recommended for general use in surgery, urology, obstetrics, gynaecology, and in eye, ear, nose, mouth and throat practice. Requests for descriptive literature and trial quantities are welcomed.

## AN EXTRACT OF ADRENAL CORTEX FOR THE TREATMENT OF ADDISON'S DISEASE

AND OTHER CONDITIONS

EUCORTONE is an extract of adrenal cortex containing the hormone cortin. It is highly successful in Addison's disease. Particularly striking is its rapid restoration of appetite, weight, strength and feeling of well being

Successes have now been reported from the use of adrenal cortical extract in various other conditions including neurasthenia, psoriasis, and hyperemesis gravidarum.

IN ACUTE TOXAEMIA OF BURNS—*Lancet* 1935 June 20th p 1400

Three cases of acute toxæmia from burns were treated with EUCORTONE and recovered. In 140 of the cases, death within a short time could have been predicted almost certainly. In the investigators' experience of these conditions recovery under any methods of treatment previously used had not occurred. The investigators attributed the recovery in these cases with every confidence to EUCORTONE

EUCORTONE is biologically standardized on adrenalectomized animals. It has now been further purified and concentrated. It is practically free from nitrogen and adrenaline contains no irritant or toxic substance and is sterile. One c.c.m. of the extract is equivalent to 75 grams of adrenal cortex or about 110 grams of the whole gland. EUCORTONE is administered intramuscularly, intravenously (in crises) and subcutaneously (in chronic cases)

## Nervous Disorders

'SANATOGEN' exhibits Phosphorus and Albumin *in a form readily assimilated by the organism*. As a deficiency of these elements is invariably associated with cases of Nervous Disorders, 'SANATOGEN' by making good this deficiency exerts a restorative and revitalising effect on the debilitated nerves. It is an axiom that both general and local diseases of the nervous system can be influenced for good by careful attention to the conditions of nutrition in the individual cases. 'SANATOGEN' is definitely indicated, for in addition to being readily absorbed it also increases the absorption of other foods and increases their nutritive values.

An article on *The Treatment of Neurasthenia and Allied Conditions of the Nervous System*, by M.D., D.P.H., states —

"Amongst the many preparations I have tried, I find Sanatogen reaches more nearly the ideal than any other. Of its ready and complete absorption there is no doubt. Its food value is best observed clinically, and the cases which I have included in this paper amply show that in this respect it is of the highest value.

"The combination of casein with glycerophosphate of sodium makes Sanatogen peculiarly useful for cases of neurasthenia: the well known properties of the glycerophosphate salts in nervous diseases of the neurasthenia type needing no further comment.

"Sanatogen is a valuable preparation in those forms of neuralgia or neuritis not associated with the presence of any local irritant.

"The value of Sanatogen as an aid to digestion as well as a food is well illustrated by the following —

Case V. H.C., Aged 3½ years, suffering from marked dyspepsia, loss of appetite, and had lost 10½ lbs in weight during his two months' absence. He was ordered two teaspoonfuls of Sanatogen thrice daily, and ordinary diet. At the end of a week his indigestion had entirely gone, his appetite was normal, and he had already increased 2½ lbs in weight.

Solely by all Chemists  
and Druggists

DOSAGE. For children and adults two teaspoonfuls three times daily or according to circumstances. For infants 1 teaspoonful added to each bottle feed.

PRODUCT OF THE  GLAXO LABORATORIES

*Well-tried and successful dried milk foods, graded to suit bottle-feeding requirements from birth to weaning*

**EASY** The method employed in **DIGESTIBILITY** preparing Ostermilk ensures that the curd precipitated in the stomach is light, flocculent and easily assimilable. Moreover, the fat and protein content are diminished to suit the digestive capacity of the infant. The formula of Ostermilk No. 1 approximates to that of human breast milk. It is suitable also for premature and weakly babies. Ostermilk No. 2 is a full cream, full protein dried milk introduced usually at the third or fourth month, and thereafter for the remaining months of bottle-feeding.

**CONSTANCY OF COMPOSITION** Constancy of composition is an accepted feature of Ostermilk. Its proportions of protein, fat, carbohydrate, vitamin D and iron are clearly and informatively stated.

**PROPHYLACTIC CONSIDERATIONS** The declared content of vitamin D in Ostermilk is able to play a calculable part in preventing the onset of rickets. Ostermilk also

contains 5 parts of iron per million (as against 1.7 parts per million in ordinary cow's milk), an estimable factor in prophylaxis against nutritional anaemia.

**VIRTUAL STERILITY** Continuous Bacteriological tests at every stage of the manufacture of Ostermilk show that virtual sterility is rigorously maintained. Packed in specially sealed tins, Ostermilk is also safeguarded against deterioration and against most risks of domestic contamination.

**SIMPLICITY & ECONOMY** Ostermilk is prepared by the simple addition of hot water. No complicated instructions are necessary, no routine supplementary medicaments are required. Mothers can therefore be trusted with Ostermilk. Economy is another special advantage of Ostermilk. It maintains the high standard of all G. L. products at a price which makes it available through chemists to every class of patient.

## THE CHANGING GROUND OF SURGERY\*

BY

W. H. OGILVIE, M.D., M.Ch. Oxon., F.R.C.S.

*Surgeon and Teacher of Clinical Surgery, Guy's Hospital*

The student of surgery must be grounded in a teaching that has the foundation of tradition or in other words the continuous approval of the best minds of many years behind it only when his feet have been thus firmly planted on the solid rock of accepted doctrine can he advance to greater heights along paths of his own discovery. But the practising surgeon should contemplate change rather than immutability for in the simmering theories of to-day are crystallizing the orthodoxies of to-morrow. Change is always with us and it is interesting to look over the period of our own experience and to consider how far surgery has changed in that time what have been the forces impelling those changes and in what direction they are likely to lead us in the immediate future.

We must take into account that gradual rise in the station and training of the surgeon himself that has been in progress over many centuries but has reached its culmination only in the present one. Surgery originated in the need for members of the religious orders who first had a monopoly of medical practice to employ what we should now call technicians for the manual part of their work. This view of the subservient position of surgery which inspired the now coveted title of *Mister* persisted till the war in the practice of admitting abdominal emergencies to medical wards where the physician made the diagnosis and summoned his colleague to hear his views and carry out his suggestions. It was often justified for though many instances might be cited of surgeons who were scientists and men of letters the majority reached their positions by force of character decision and manual dexterity, and few had a scholastic record equal to that of their medical contemporaries or undertook postgraduate study in any science but anatomy. Now however the scholars and best students in our medical schools seek surgical posts and having become surgeons find their College taking the lead in research of every kind and offering them facilities to work out their own ideas and help and encouragement in their difficulties.

Thirty years ago it was the highest praise to call a surgeon a brilliant operator to-day such an encomium carries the same slight as to say that a girl has a kind heart—the implication that more important merits are lacking. The operation is regarded as part of a plan of treatment which precedes and follows it till its object has been attained rather than an isolated *tour de force* and interest centres more in measures to eliminate its risks and counteract its effects than in the development of spectacular technique. The details of asepsis have been improved one by one till chance infections are almost unknown. The sterilization of gowns and dressings is

now certain rather than hoped for the air in most modern theatres is conditioned—that is washed filtered and rendered bacteria free before being put into the room some enthusiasts have even introduced a ring of mercury-vapour lamps round the operating light following the suggestion of Hart of Connecticut to sterilize the air over the working field itself. But air and dust borne organisms are usually non pathogenic or of low virulence and do not constitute a danger comparable to that of the human streptococcal carrier. It has lately been shown that where a presumably clean case has been infected by a streptococcus an identical organism can nearly always be recovered from the throat of some member of the operating team who may as yet have no symptoms. The risk of such infection disappears if masks containing a layer of callophane are worn by all those taking part in the operation.

### Synthetic Drugs for Infections

For declared streptococcal infections we have a new and in most cases a potent remedy in sulphanilamide. This drug is no more than two years old but it is familiar and used by all of us. In surgery apart from its value in chance infections it has entirely altered the outlook in some of our commonest and most distressing problems notably infections of the hand. A tendon sheath or tissue space infection formerly meant a ruined hand usually a ruined life. Following Kanavel's anatomical researches the operative treatment was put on a sound basis and many hands were saved with perfect function but in all except the earliest cases the result was still imperfect. By the use of sulphanilamide in combination with early and correct incision the period of active infection and necessary drainage is now reduced to a minimum and the good function that can only come with early healing results.

Almost more encouraging than the particular applications of sulphanilamide is the general promise that it brings. Since the days of Pasteur chemists have been chasing the ideal of an agent lethal to bacteria that will act in the body. They have produced a series of antiseptics said to be effective in septicaemia when given intravenously but proved in practice to do more harm to the host than to the invader. Salvarsan seemed to promise a new era but the group of arsenical preparations it introduced were soon found to be active against protozoa but not against bacteria. With the standardization of the arsenicals and the increasing production of drugs by synthesis rather than extraction with the apparent limitation of remedies to the amelioration of symptoms and the lack of any of proved efficacy in bacterial diseases it seemed that the pharmacologist was bound to disappear.

## THE CHANGING GROUND OF SURGERY

## Duodenal Ulcer

the rush and the excitement of the modern world, the methods of surgery are changing, so that we never prepare a lecture to students in the same way that diseases are changing in the passing years, that diseases are not what they were. They, too, have their enemies, and natural immunity, medicine, surgery, and public health have all combined to eliminate the favourites of pre-war days.

## The Decline of Syphilis

Bacterial diseases, like tribal migrations, are most calamitous when they first descend on a populace unprepared for them, with time, resistance is organized, the invaders weaken and finally disappear. Syphilis ravaged the world at the close of the fifteenth and beginning of the sixteenth century, it remains a scourge, but its manifestations, even in untreated cases, are becoming milder. Tuberculosis is even more evidently doomed to extermination by the gradual development of natural immunity. Its incidence and its mortality have both dropped steadily during the last fifty years, and the satisfaction which we as doctors might take from this fact is shaken by the notable absence of any acceleration in the downward curve when Koch discovered the organism or when open-air treatment was advocated. The youngest student to-day will probably see tuberculosis vanish from the face of the earth.

Medicine, or rather therapeutics, by the improved drug treatment of syphilis has abolished almost entirely the third stage of that disease. In 1910 about one quarter of the patients whom I saw on surgical and dermatological out-patient rounds came for some manifestation of tertiary syphilis. In the last six months I have found only a single gumma, and that a doubtful one. Surgery, by the routine repair of herniae and the early treatment of urethral stricture, has almost wiped out strangulation and extravasation of urine, the 'high lights' of a pre-war emergency week. Radium and x-ray therapy have claimed most cancers, apart from those of the alimentary canal. Public health and improved economic conditions have reduced the incidence of gastric ulcer and put rickets and osteomyelitis into the ranks of the rare and disappearing diseases.

Lest you should think that these remarks are a prelude to a swan song of surgery, I would hasten to say that there is always a new generation of disease knocking at the door. The very advance of civilization, which has removed those troubles due to poverty and ignorance, is bringing others peculiar to itself. I can mention only two factors that seem to be operative: the rush and the strain of the competitive element, and the constant feeling of insecurity in modern life, and the unnatural diet, consisting largely of foodstuffs preserved to be eaten long after their time of preparation and far from their place of origin and therefore robbed for canning purposes of all portions that cannot be proved to have a high nutritive or vitamin value. These factors are responsible for the appearance of new diseases and the increase in old ones due to nervous stress, the other for the apparently increasing incidence of infections of the alimentary tract. Both bring new problems to surgery.

Duodenal ulcer is essentially a disease of civilization, and we shall appreciate more fully if we try to dissociate it in our minds from gastric ulcer. The chief causes of gastric ulcer seem to be sepsis, undernutrition, or faulty diet, and trauma caused by insufficient mastication and the angulation of ptosis, the typical gastric ulcer patient is a timid, depressed, and sedentary old lady, with poor muscle tone and a low acid curve. Duodenal ulcer, on the other hand, is associated with worry, overwork, and the excessive smoking that accompanies these two, the duodenal patient is a live wire, a go getter, a high pressure salesman, a hundred per cent man, thin, restless, with a small stomach and hyperchlorhydria. His type is increasing, and so undoubtedly is duodenal ulcer, and for the first time it is becoming fairly common in women. While this increase in duodenal ulcers is undoubted, I cannot support it by my own figures, since my records concern cases coming to operation, and in them gastric ulcers predominate largely. I find that much of my time at the out-patient department is spent persuading gastric ulcer patients to have an operation and duodenal patients not to have one. Gastric ulcer, if medicine has not cured it early, is a surgical disease, and the results of excision are excellent. Duodenal ulcer is the outcome of high pressure living: if the patient can be persuaded to mend his ways the ulcer will disappear without surgery, if he cannot, surgery, unless it is of a most drastic nature, will give him only temporary benefit. One of the most manifest changes in the surgical outlook within recent years is that the great body of men of experience and judgment are agreed that in duodenal ulcer operation should be reserved for the complications—perforation, stenosis, and severe haemorrhage—and not be looked upon as a cure for the ulcer tendency.

## Operation for Graves's Disease

Graves's disease, again, is a malady which is very constantly associated with emotional shock. Many of the functions of the thyroid gland are understood, but its place in the complicated corporation of ductless glands, whether that of a director or merely of a bulky foreman, is not yet unravelled. Crile looks upon the thyroid as the regulator of constant energy output as the adrenals are of intermittent outbursts. He points out that the great majority of animals are either hunters or hunted, always alert for attack or escape, always ready to spring from rest to intense activity. Two creatures alone are lords of all they survey—man on the earth and whales in the ocean—and in them alone does the thyroid exceed the adrenals in weight. The definite association of thyroid activity with the important phases of woman's life—puberty, menstruation, and pregnancy—and the frequency of all thyroid diseases in females, might be cited in further support of Dr Crile's contention that thyroid dominance is the mark of a superior place in the scale of creation. Be that as it may, Graves's disease has hitherto been almost exclusively in women, and chiefly in young women of the age when emotional crises are common. Within the last few years an increase which is apparent to every surgeon interested in thyroid work has been noted in the incidence of Graves's disease in men, almost entirely of intermediate social position. The millionaire may be worried, but they are not serious enough to affect the thyroid, the labouring man can put all his troubles on the broad shoulders of the State, but the clerk with 40 with an increasing family and no promotion in the small business man threatened by poverty

the schoolmaster uncertain whether he can hold in his job—these people must carry their responsibilities alone and they are showing the strain by developing hyperthyroidism. It is indeed fortunate that the active treatment of Graves' disease has been transformed within the same period from a clumsy and fairly sound procedure to one of the safest and most satisfactory in surgery. One cause is the worthy circle (for not all circles are vicious) that good results bring patients at an early stage and fitter patients mean yet better results. Another is the use of iodine which though it has no curative action yet enables the physician by doses checked against frequent basal metabolic estimations to bring any goitre patient to the condition of a normal individual for a few days and to predict to his surgical colleague when that time will come. Yet another is the standardization of operative procedure to a bilateral subtotal excision of the thyroid gland leaving no more than two cubic centimetres of gland tissue on each side in the tracheo-oesophageal groove. Most important is the division of labour between the physician and the surgeon the former accepting responsibility for the preparation for living the date of operation and for the after care the latter content to work under orders and do no more than guarantee to return a live patient with a respectable scar covering a job neatly done.

### The Problem of Arterial Hypertension

Most alarming among the problems presented to surgery to day is that of arterial hypertension. High blood pressure with its consequences is nothing new and many famous men have died of apoplexy or lost their fire in the dotage of cerebral softening. But they were old and reached this last infirmity of noble minds after a long life of scorned delights and laborious days. The tragedy of the present time is that men and women are succumbing to the stress before they have time to bring their ideas to maturity or to reap the reward of their labour. Still under 30 they are stricken with intolerable headaches and failing vision and find themselves unable to concentrate without a further increase in these distressing symptoms which are the outcome of a systolic pressure that may be from 200 to 300 mm. of mercury.

Such a problem has naturally received the fullest attention from research workers particularly in America where this scourge of the intellectual is increasing rapidly. Hypertension does not occur spontaneously in animals but it can be produced by applying a clamp to the renal pedicles and closing it gradually. If the arterial supply is so reduced that the nutrition of the kidneys is impaired albumin and casts appear in the urine and a condition comparable to the hypertension of renal disease in man is reproduced. But by gradual occlusion a point can be reached short of renal damage where the systolic pressure of the animal is raised and remains up as long as the clamps are kept on the pedicles. The hypertension thus produced resembles non renal or essential hypertension in man but is certainly not identical. Experimental hypertension persists as long as the obstruction to the blood supply of the kidneys is maintained. It is not a reflex effect for it remains when all nerves to the kidney have been divided and even when one kidney is removed and the second transplanted to the thigh—an irrefutable denervation. It may be lowered by various operations such as transection of the cord designed to dilate the arterioles of a wide area but this depression is temporary. It appears likely therefore that the hypertension is due to some pressor substance produced in the kidney when its blood supply is jeopardized.

In man on the other hand the blood pressure can be lowered in many ways. Surgical alleviation of these victims of an intellectual machinery that has run its bearings was first suggested by the profound fall in systolic pressure that follows a spinal anaesthetic and the operations performed to day have all been designed to remove the vasoconstrictor impulses from a large part of the splanchnic vascular bed. Whether the resulting benefit is due to reduced peripheral resistance in the arterial tree or whether as seems more likely in view of the experimental evidence mentioned above it depends upon the denervation of the renal vessels alone—the removal of Nature's renal clamp—is uncertain. Many alternative procedures are undergoing trial. Their relative merits are still undecided the choice of suitable patients varies from surgeon to surgeon and the benefits that may be expected from any or all of them have still to be assessed.

### Operations for Raised Blood Pressure

Heuer at the Cornell Medical Centre New York performs lumpectomy and divides the anterior roots of the lower six dorsal nerves. Max Peet at Ann Arbor does a bilateral extrapleural operation above the diaphragm. By removing no more than an inch of the eleventh rib on each side he is able to resect the three splanchnic nerves as they reach the diaphragm and the two lowest ganglia of the thoracic sympathetic chain. He insists that the least splanchnic must be found and excised if possible as it carries the renal vasoconstrictors. Adson at the Mayo Clinic approaches the splanchnic nerves just below the diaphragm through a long incision along the outer border of the erector spinae from the eleventh rib to the iliac crest. Retracting the kidney in its fatty envelope forwards he follows the last dorsal nerve to the crus of the diaphragm and finds the great splanchnic nerve. He divides this and drawing out the semilunar ganglion which it enters removes the greater part of it coagulating it by diathermy before cutting to avoid the risk of haemorrhage. In addition to the three splanchnic nerves he removes the upper two lumbar ganglia. Crile at Cleveland denervates the adrenal and removes the semilunar ganglion through a smaller lumbar incision working with long blunt dissectors and scissors guided by touch.

Each of these operations appears to have its advantages and drawbacks its successes and failures. To the visitor with little personal experience who must base his opinion largely on technical criteria Peet's operation appears the best. It is the only one apart from Heuer's in which both sides can be done at a sitting it is bloodless and though the field is limited access to all parts of it is adequate and vision excellent. Adson's operation is in his hands a masterpiece of neat work. The important part is however carried out at the limits of a deep dissection aided by exact retraction and well placed lights and it would seem that any chance bleeding at this stage would be controlled with considerable difficulty. These doubts apply with greater force to Crile's blind operation which would probably be very dangerous in the hands of any surgeon not possessing his unrivalled experience and delicate touch. Division of the anterior spinal roots inside the theca seems needlessly severe in its approach and destructive in its scope.

The results obtained after operations for hypertension seem to vary in the most remarkable manner even in groups that should be comparable—that is in patients of similar age with an identical clinical syndrome and treated by the same operation. As might be expected therefore surgeons differ considerably in their indications for opera-

tion, in their criteria of operability, in the enthusiasm with which they regard this branch of surgery, and in their outlook on its future. At one extreme Adson will only accept for treatment a small group of picked patients. They must at any rate be under 50, and preferably under 40, and must have a sound heart and good kidneys. They are first put to bed and their blood pressure taken every hour for twenty-four hours or longer to establish a normal. They are then subjected to several tests. Five per cent pentothal sodium is given intravenously till there is no further drop in blood pressure, three grains of sodium amytal by mouth every hour for three successive hours, and six half-grain doses of sodium nitrate at half-hourly intervals. If the blood pressure returns to normal, or nearly normal, with all these tests that patient is considered suitable for operation, but if it does not it is assumed that the hypertension is due almost entirely to organic changes in the arterial tree and that it will not be improved with surgery. At the other extreme is Max Peck, who finds that some of the cases that appear most unfavourable show dramatic improvement, if not cure, and, while he carries out a thorough preliminary investigation and vasodilator tests, is willing to operate on any case that does not show obvious renal damage.

One of the wisest surgeons in the United States, himself a neurosurgeon, told me that he felt as yet quite unable to foresee the ultimate outcome of this work, but he thought it was well worth continuing. A symptomatic improvement seems to occur in every case—that is, the patients lose their headaches, and their vision improves—but in many of these there is no appreciable drop in the systolic pressure to explain the improvement. Some, though their pressure remains unaltered, become sensitive to drugs such as cyanates to which they were formerly resistant. Many show a fall in blood pressure of about half the amount by which they exceed the normal, but after a few months they start to climb, and by the end of the year have reached their former figure. A few return to normal or near normal, and remain at that level. Four years ago a surgeon of about 40 was forced by a rising blood pressure, inability to concentrate, headaches becoming at times intolerable, and failing vision to resign his university post and abandon his practice. He underwent the operation of bilateral splanchnicectomy, and immediately lost all his symptoms and returned to a normal blood pressure. He obtained another post at a university in another State, and has been in full work ever since, his blood pressure showing no tendency to rise again. I had not the good fortune to meet him, but I met many of his colleagues, and they all agreed that he was now able to work as hard as any of them. To my question as to whether he was as good a man as before his symptoms appeared they replied that he had lost some of his fire, he was not the "go getter" he used to be, but he was still a fine surgeon. Many of us are apt to become less energetic between 40 and 44 without the excuse of an operation to explain it, and would count the loss of some enterprise a small price to pay for rescue from idleness, imminent blindness and impending death. It is cases like this—and they are by no means rarities—that illustrate the real value of surgery in hypertension, and provide a reason for its fuller study.

#### Increased Incidence of Appendicitis

That infections of the alimentary tract are on the increase is undeniable to one who surveys the change in surgery over even a brief period. I was sufficiently impressed by this increase in 1923 to attempt an experimental

investigation of its cause that formed the basis of a Hunterian lecture the following year. In that lecture I sought to prove that bacteria are normally carried through the intact wall of the alimentary tract, and that in conditions of injury or stasis the number passing through is considerably increased. I suggested that such stasis is in almost inevitable sequel of the modern dietary, which differs from that of our ancestors in two main respects: the high degree of preparation to which our cereals are subjected, robbing them of many vitamins, and the smaller and still lessening amount of indigestible material, chiefly cellulose, which we consume.

Whatever its cause, the most striking manifestation of this increase is seen in appendicitis, which first appeared as a relatively common disease at the beginning of the century and has since become more frequent every year. Some would explain this appearance and increase by saying that appendicitis was formerly just as common but seldom diagnosed. The clinical acumen of our predecessors cannot be assessed, but their post mortem reports survive in their detailed thoroughness, and it is very unlikely that the association between peritonitis and a gangrenous appendix would have escaped the eyes of men like Gull and Wilks. Bright described infection of the vermiform appendix in 1839, but did not look upon it as a common disease. Others, again, ignore this increase in their attempt to find statistical support for a revival of the pre-Listerian treatment of appendicitis by procrastination. They point to a slight rise in the total mortality for appendicitis in Britain over a ten-year period as evidence that early operation has not lowered the death rate, omitting to allow for any increase in the total incidence of the disease. An examination of the hospital records of South-East London, however, shows that during the same period, while the number of deaths has risen by 8 per cent only, the number of operations for acute appendicitis has increased by 260 per cent.

#### Irritable Bowel and Ulcerative Colitis

Ulcerative colitis is another alimentary tract infection which, though old, has become common only during the present century and a subject for surgical attention during a much more recent period. The term is used, somewhat loosely, to describe a group of disorders of the large intestine characterized by the passage of frequent loose stools containing mucus and often blood. Three conditions at any rate must be excluded before the label of ulcerative colitis is applied. The first and most important is that of "irritable bowel" or "maltreated bowel," which becomes a disease when it is labelled mucous colitis. The distal colon is richly set with mucous cells whose purpose is to lubricate the normal excreta in transit, and whose habit is to pour out mucus when abnormal constituents appear. The bowel consciousness instilled by infant training becomes, in those lacking the interests of work or a family—that is, the wealthy—an absorbing passion that has made the fortunes of countless drug manufacturers, fashionable physicians, health resorts, and irrigation parlours. The vested interests that profit by the colitis complex are indeed so powerful that it is only a few bold spirits like Hurst who have dared to point out that habitual constipation is usually the result of habitual purgation, that intestinal intoxication is caused not by stasis but by the drugs given to relieve it, and that Plombier's treatment can wreck the healthiest colon in a few weeks. The patient with mucous colitis can never always be put right if her drug chest, which will be too full to overflowing, is emptied into the dustbin and she put on a rational diet and exercises.

The second condition that must be excluded is multiple polyposis a disease that may be suspected when there is a history of others in the family similarly affected and that can usually be recognized by sigmoidoscopy or contrast radiography. Apart from its complete intractability polyposis nearly always goes on to cancer and therefore demands excision—segmental in those rare instances where part of the colon can be proved to be free total colectomy in the majority. The third condition to be excluded and treated by the appropriate serum is bacillary dysentery. There remains a large group that must be classed as true ulcerative colitis a disease for which specific streptococci have been held responsible by Bargen and others but about whose primary cause no agreement is yet possible.

The medical treatment of ulcerative colitis does not concern us here except to know that it sometimes fails and that these failures provide a new problem for surgery. Between the successes and the worst failures those patients who have gone progressively downhill and are poisoned and bloodless lies the intermediate and most important class of those that are bound to fail but are not yet at the point of death and therefore provide the most promising material for surgical treatment. When the colon has at last been got to heal after prolonged ulceration when its wall is thick rigid and fibrous and the scars on its mucous coat are covered with a single layer of non glandular epithelium it may at last be a reasonably efficient sewer while it is flushed out repeatedly and asked to transmit no more than paraffin lubricated pulp but it cannot function as a colon and is bound to ulcerate afresh on the first attempt to restore normal diet at the first period of lowered resistance.

### Surgery of the Ulcerated Colon

The surgical treatment of the ulcerated colon may be divided into three stages—rest excision and restoration. Rest of the diseased bowel can be obtained only by complete transverse division of the ileum six or eight inches above its termination. Appendicostomy and caecostomy have both passed into disavour the feeble flushing of the colon which they allow does not appear to be as effective as washing out through the rectum and neither of them rests the colon to an appreciable extent. Transverse ileostomy however diverts the whole intestinal flow to the surface. The colon no longer filled with bacterial pabulum mechanically irritated or stimulated to contract rapidly becomes more healthy. It is not to be expected in the advanced type of case in which such a grossly destructive operation as colectomy has come to be considered that it will recover sufficiently to function again but the discharge becomes one of purulent mucus rapidly decreasing in amount bleeding gets less or stops entirely and the absorption of toxins is diminished when infected fluids no longer reach the ulcerated surfaces and mass movements do not and the lymphatic and venous flow. Almost as important as the mechanical exclusion is the fact that the diet need no longer be chosen to spare the colon. Part of the difficulty in treating the disease is to provide a diet that gives a minimum residue yet is varied appetizing and sufficient in all elements. After ileostomy the patient may be fed on anything and everything and this alone causes a marked improvement. To start with the ileal efflux is watery and almost continuous dehydration is apparent and the skin round the opening is sore. But the capacity to absorb water is soon acquired and the outflow takes the consistency of putty and is discharged at intervals that may be as long as four hours.

As soon as the patient's condition will justify a further operation the diseased colon is removed. It can usually be resected down to the lower part of the pelvic colon or even the pelvic rectal junction in one stage but no more need be done than the difficulties at the time and the reaction of the patient to operation will allow the proximal end of the remaining colon being brought to the surface when the incision is closed to form the start of the next stage. With the patient fit again after colectomy restoration is undertaken if it is considered advisable when the disability and the gain to be attained are set against the difficulty and severity of the operation. When the lower half of the pelvic colon and the rectum have been spared restoration implies no more than implanting the ileum in the stump of the pelvic colon and is obviously the right course to be adopted. But since ulcerative colitis usually starts in the rectum and affects the rectum and pelvic colon more than any other part excision of the rectum is necessary in most cases to eradicate the disease. It also seems an essential preliminary to satisfactory water absorption from the ileum. When the rectum has been excised restoration or the normal means implantation of the distal ileum in the anal sphincter and implies first a conservative excision of the rectum which in the presence of ulceration and perirectal fibrosis may be almost impossible and later a difficult dissection to reopen the old rectal bed and transfer to it the mobilized ileum.

### Regional Enteritis

Crohn's disease or regional ileitis can lay as just a claim as any to be a new disease for it was first described as an entity by Crohn Ginzburg and Oppenheimer in 1932. Single cases had been reported as rarities by previous observers but these authors were able to study a series in Mount Sinai Hospital and to establish the clinical and pathological features of the condition. Since their paper it has been shown that the changes peculiar to this infection are not limited to the lower ileum but may occur higher and even in the jejunum so that regional enteritis is probably a better term than regional ileitis.

Regional enteritis is a non specific granulomatous infection of unknown aetiology progressing steadily and ultimately fatal unless treated surgically. The affected segment of bowel is thickened rigid and red or purple in colour. Its lumen is reduced usually to the diameter of a pencil or even smaller. On laparotomy the appearance is characteristic the thickened rigid bowel the sharp demarcation at each end of the affected segment and the extensive involvement of the mesentery over the same area being unlike anything else. In microscopical section the wall of the intestine is seen to be almost entirely replaced by vascular granulation tissue with large foreign body giant cells but all tests for the tubercle bacillus are negative.

Clinically Crohn's disease may be met with in many puzzling forms. Perhaps the most typical picture is that of a young man or woman who has been ailing for two or three years losing weight steadily and showing obvious anaemia. During this period there have been attacks of cramp like abdominal pain accompanied by mild diarrhoea and a moderate pyrexia. Other cases progressing more rapidly resemble subacute appendicitis indeed the differential diagnosis from recurrent appendicitis may be very difficult for there is usually tenderness and often a lump in the right iliac fossa and only occasionally can this be recognized as a tubular ileum.

because of the mesenteric oedema that obscures its outlines. Others develop spontaneous mucocutaneous fistulae. In others, again, the symptoms of obstruction predominate. A barium meal will often solve the puzzle by showing a narrow rigid channel replacing the normal outline of the lower ileum.

The treatment of regional enteritis is essentially surgical. No spontaneous cures have been reported, and without operation fistulae appear or obstruction supervenes. Many patients are too ill to stand resection when they are first seen and in them an anastomosis must be made between the ileum above the disease and the transverse colon in order to rest the affected segment and avert obstruction. A few so treated may regain their health without further operation, but Mixer has found that in the majority treated by excision alone the disease is not arrested, but continues to spread. Resection of the affected segment with as much as possible of its mesentery and at least two inches of healthy bowel above and below it must therefore be looked upon as the correct treatment, to be undertaken as a primary operation in those who are able to stand it and after excision in those who are gravely ill. Since the disease commonly affects the terminal ileum, resection usually implies removal of the caecum and ascending colon in addition. It is as yet too early to speak with any certainty about the permanence of cure. Berg had no recurrences in thirty-two resections among Crohn's cases, but others have seen them. Sherris and Jackson report two separate recurrences in the same patient, each following a wide resection.

### Two Conditions for Surgical Advice

In discussing changes in surgery we must beware of accepting the view that change and progress are synonymous, that what is new is better than what went before, or even necessarily good. The study of diseases newly arrived or newly handed over to surgery provides us with interest but our enthusiasms should be reserved for those changes, often very simple ones, that lead us to something better. If we consider any condition now treated by surgery and ask ourselves, 'How can we improve the results we are getting to-day?' we can find two simple answers: first, by getting the disease at an earlier stage, before it has spread widely, before it has injured adjacent parts before the patient is ill; secondly, by modifying our operation to give the best possible results. Both of these demand not genius not brilliance or technical skill, but independent observation and constant hard work. Disease in its early days is betrayed by symptoms, signs belong to its later and less happy stages. By watching our patients carefully, by listening without prompting by recording their story, however irrelevant it may appear at the time and by comparing our notes with the exact knowledge brought to us later in the operating theatre, the laboratory bench or the post-mortem room we shall acquire a store of material from which we may be able to build new clinical pictures—pictures that we shall recognize when they come again that may allow us to disentangle new diseases from the mixed class in which they are now hidden and to recognize old ones at an earlier stage. I need only remind you that it was by such methods nothing more dramatic than Moynihan first discovered the picture of duodenal ulcer, showed it to be not a rare disease but one of the commonest, and laid the foundation of a reputation that has seldom been equalled. But it is a lesson my colleague Ryle has made contribute to our clinical science that stand as models of accurate

observation, conscientious recording, and painstaking analysis.

An outstanding example of that careful study of results which allows an old operation to be remodelled, so that it is virtually a new one and certainly a better one, is provided by the work of Dukes and Gabriel in cancer of the rectum. Dukes's dissections have shown that the spread of this growth is entirely upward in hopeful cases, have laid the foundation for a safer and more satisfactory operation, and have justified the revival of conservation of the sphincters in high and early growths. Gabriel's careful study of results has shown that what the pathologist predicts does actually take place.

### Problems for Solution

There are few problems that we cannot hope to resolve by inquiry along these two lines. We are all depressed by our results in cancer of the stomach. But if we can trace some clinical feature in the earliest phase of departure from health common to all those patients who later come with advanced growths, we may hope to get more in that very small group where radical resection is possible. If we can discover, by detailed microscopical dissection of the removed specimen, where the resections we now perform are not wide enough and learn by the study of post-mortem examinations where recurrences appear after operations that seemed hopeful at the time, we shall have knowledge that will enable us to modify and to extend our surgery in directions that will increase the proportion of cures.

Other growths will be brought within our reach by means no more spectacular. The first successful resection for cancer of the oesophagus was twenty-five years ago, but till 1936 the operation had only succeeded six times, and the mortality was within a decimal point of 100 per cent. Six months ago I saw three cases successfully treated by Garlock of New York, and two more by Wooley of Toronto—that is, five in one year by two surgeons. We may predict that the mortality of this operation, in the hands of expert surgeons, will be reduced below the present mortality in cancer of the stomach, and that the cure rate will be much higher, for oesophageal growths are of lower malignancy. We only need the clinical picture that will allow us to recognize the disease before obstruction appears.

Change is everywhere, and change is desirable, for change is life. Only when we are dead do our osteoblasts and osteoclasts cease their tireless moulding and rebuilding, and our skeletons remain a changeless memory of the shell that once held our sorrows, hopes, and fears. It is good to live in a period of change, to be concerned with the changes that are taking place in our art, to know that they are changes for the better, and to realize that among our fellow countrymen and fellow townsmen are names that will always be remembered as leaders of the advance.

At the annual meeting of the international committee of the campaign against charlatanry held during the Brussels Medical Congress on April 17 when Dr Robert d'Ernst of Geneva was elected president, the following expressions of opinion were adopted: (1) The title of doctor before the surname shall be exclusively reserved for doctors in medicine, surgery and obstetrics. (2) The practice of physiotherapy shall be reserved exclusively for qualified doctors. (3) Glasses shall only be supplied by opticians on a doctor's prescription.

# THE COMPOSITION OF THE BLOOD IN PREGNANCY

BY

JEFFREY RAMSAY, OBE, MD FRCP  
Honorary Physician and Pathologist, Royal Infirmary  
Blackburn

V T FIERLINS MB, DPH  
Medical Officer of Health, Blackburn

AND

H E MAGILL, DSc, MB

In this country studies of the composition of the blood during pregnancy have been mostly confined to the haemoglobin and cellular elements, other constituents such as calcium and phosphorus which are also important during gestation seem to have attracted little attention. The same can be said of the enzymic phosphatase which is concerned with the metabolism of these elements. These blood constituents and the haemoglobin were determined in pregnant women attending the Blackburn Corporations ante-natal clinics and tests of the bactericidal power of whole blood against streptococci of human origin were also carried out in the hope that the results would throw some light on the susceptibility of the subject to puerperal infection. The original aim had been to secure at least 200 subjects and to classify them so far as possible aetiological in accordance with the signs and symptoms of illness during pregnancy labour and the puerperium. Unfortunately the number of volunteers fell off rapidly after the first few months and it was consequently decided to wind up the study when analyses of the blood of 101 subjects had been made. The results are published in the hope that they will prove of some value to those contemplating a similar type of inquiry.

## The Investigation

This began in July 1936, and lasted for about one and a half years. The subjects consisted of all those attending the ante-natal clinics who agreed to have their blood sampled. They were not chosen for health economic or any other reasons but it is not claimed that the volunteers are an average sample. It is possible that the material may have been biased by self selection.

About 17 ml of blood were necessary for the analyses and as it appeared unlikely that many women would submit themselves to more than one blood sampling a suitable period of gestation had to be chosen for this. The seventh month was selected. The final months were avoided because of the likelihood of objections by the subjects in view of the near approach of labour and the early months because it seemed probable that the period of gestation would not have advanced far enough to induce detectable alterations in the composition of the blood.

The blood was taken in the ante-natal clinics at about 11 a.m. and the haemoglobin percentage was estimated at the same time. One sample was taken for biochemical analyses and another for the bactericidal test. The former amounting to about 12 ml was allowed to clot and the analyses were done on the serum. The sample for the bacteriological test was about 5 ml and was drawn separately into a sterile test tube containing enough powdered potassium citrate to prevent coagulation. The samples were delivered to the laboratory of the Royal Infirmary Blackburn about half an hour after being drawn. Determinations of inorganic phosphorus and

phosphatase were generally completed by about 3 o'clock on the same day and that of calcium the next morning. The bactericidal test was usually finished on the morning of the second day after sampling. The following were the methods employed.

**Haemoglobin.** Dare Inorganic phosphorus and phosphatase. Bodanvsky (1932-3 1933) adopted from Kuttner and Lichtenhan (1930) Calcium Clark and Collip (1925).

**Bactericidal Test.**—A primary broth culture of streptococci from a case of puerperal septicaemia was grown. A tube of blood broth was then inoculated with this culture and after growing for about fifteen hours it was put in the ice-chest and kept there for the parent culture for the tests. Every week cultures were conducted to see if this parent culture was still virulent and on dates of ordinary bloods were inoculated from it. A tube growing to fifteen hours the broth was diluted with 10 ml of 0.9% saline to the required standard (Burroughs' Wellcome No. 10). This strength was used throughout the week to inoculate the blood samples. Three standard loopfuls of the culture were added to each 5 ml of whole blood and incubated for three hours when a subculture was made on plate and examined after eighteen hours incubation for streptococci.

The haemoglobin estimations were done by D. T. Hey, and in a few cases by other medical officers of the Health Department Blackburn all of whom had had previous experience with the Dare instrument. The biochemical and bactericidal tests were carried out by one of us (J.R.) in the laboratory of the Royal Infirmary, with the technical assistance of Messrs. Floyd and Pomret.

## Results

The average values and ranges are shown in Table I. The mean values are haemoglobin 7.3 per cent.

TABLE I.—Haemoglobin (Dare) Calcium Inorganic Phosphorus and Phosphatase Contents of Serum Averages and Ranges and Bactericidal Power of Blood of Women at the Seventh Month of Pregnancy

	Hb per cent	Calcium mg./100 ml	Inorganic phosphorus mg./100 ml	Phosphatase Dare's Units	Bactericidal Power—Streptococci	
					No. Growth	Growth Sp. per
Mean	7.3	9.34	2.7	2.3	7	2
Standard deviations	1.23	1.25	0.55	0.95		
Ranges	4-10.3	6.0-13.7	1.3-4.0	1.0-6		
Number examined	93	90	97	9		99

calcium 9.34 mg inorganic phosphorus 2.7 mg. and phosphatase 2.39 units per 100 ml of serum. Growth of streptococci indicating a low bactericidal power of the blood occurred in twenty-two of the ninety-nine women tested.

The literature on the subject of the haemoglobin and cellular contents of blood in women is voluminous and it will only be possible to refer to those publications which are the most relevant. Recent work on the haemoglobin content of the blood of pregnant women has been summarized by Boycott (1936) but unfortunately the exact period of pregnancy is not stated so that comparison with our figures is not strictly applicable.

## HAEMOGLOBIN CONTENT

In thirteen healthy American women at the twenty-sixth to thirty-fifth week of pregnancy Diekmann and Wegner (1934a) obtained an average value of 12.2 grammes of haemoglobin per 100 ml equivalent to

88.4 per cent (Haldane). The average value obtained in our series, 77.8 per cent (Dare), is equivalent to 90.2 per cent on the Haldane scale, since 100 per cent haemoglobin on the former instrument is equivalent to 16 grammes of haemoglobin, and 100 per cent on the Haldane instrument is equivalent to 13.8 grammes of haemoglobin per 100 ml. The average value found in our series therefore differs but slightly from the figure obtained by the above-named workers.

It is well known that the haemoglobin content of the blood falls during pregnancy. Dieckmann and Wegner (1934a) found that it fell steadily in thirteen healthy women to a minimum of 88.4 per cent at the seventh month after which it increased slightly until the end of the period. The fall in haemoglobin has been attributed to hydramnia and the findings of Dieckmann and Wegner (1934a) go to support this view. They observed that an increase occurs in the total plasma of the blood, and that the amount of the increase is relatively greater than that which takes place in the total number of red cells and in the total haemoglobin in the body. There is, however, evidence of the occurrence of actual anaemia, presumably physiological. Thus the same observers (1934b) found that

the saturation index,  $\frac{\text{Haemoglobin per cent}}{\text{Volume of packed red cells per cent}}$ , is below that in the non-pregnant state from the sixteenth week until full term.

The Dare instrument reads approximately 10 per cent lower than the Haldane and since values less than 80 per cent on the latter scale are generally considered to be indicative of anaemia, we may regard 70 per cent as the critical point on the Dare scale. But since Dieckmann and Wegner (1934a) showed that the haemoglobin falls by about 15 per cent on an average at the seventh month of pregnancy compared with the non-pregnant state we may regard 60 per cent on the Dare scale as the approximate critical point when dealing with pregnant women at the seventh month. On this basis seven of the subjects were anaemic (see Table II). Values falling within the

TABLE II—Distribution of Values of Haemoglobin and of Calcium, Inorganic Phosphorus and Phosphatase of Serum of Women at the Seventh Month of Pregnancy

Haemoglobin per cent				Calcium mg./100 ml.				Inorganic Phosphorus mg./100 ml.				Phosphatase Units per 100 ml.			
Below 60	60-69	70-79	80	Below 8	8-8.9	9-9.9	10+	Below 2	2.0-2.9	3.0-3.4	3.5+	Below 2	2.0-2.9	3.0-3.9	4+

range 60 per cent to 70 per cent may be regarded as on the borderline of anaemia. There were eighteen such cases in the series making twenty-five out of the ninety-five tested or 26 per cent who were either definitely anaemic or on the borderline of being so. Two women whose haemoglobin was less than 60 per cent passed through pregnancy, labour and the puerperium without any significant signs or symptoms of ill health. It has been observed by many practitioners that low even very low haemoglobin values are compatible with fairly good health. On the other hand the risk involved in diagnosing anaemia on inspection only is shown by the fact that a few women who were diagnosed clinically as anaemic had haemoglobin values ranging from 70 to 87 per cent.

#### BLOOD CALCIUM

The range for blood calcium in normal adults is given as 9 to 11.5 mg per 100 ml by Peters and van Slyke (1931). Mull and Bill (1933) found that the blood calcium in 94 per cent of 207 healthy non-pregnant women of child-bearing age was from 10 to 11.5 mg per 100 ml. The same workers (1934) observed that, on the average, the minimum value in 900 healthy pregnant women was reached at six weeks before term between June and December, the mean being 9.89 mg. When labour set in between January and June a slightly lower minimum of 9.61 mg, on the average, was obtained. The last figure indicates a fall of about 11 per cent compared with the middle point of the range they obtained in non-pregnant women. On the same basis our average value of 9.34 mg for ninety-six women indicates a fall of about 13 per cent at the seventh month.

Of the total of ninety-six determinations of calcium, thirty-seven (39 per cent) are less than 9 mg per 100 ml. The remarkable constancy of the blood calcium level in health, as well as the literature cited above, suggests that values below 9 mg are too low for good health, but we have no evidence to indicate the exact cause of these low values. It should, however, be pointed out that nearly all the 101 cases received from the clinics supplemented with vitamins A and D and some also of iron.

In 120 healthy and unhealthy pregnant women Ishok and Toussaint (1936) obtained values of from 5.4 to 13.2 mg, with a mean of 9 mg, per 100 ml. The mean for those of the group who were suffering from leucorhoea was 9.5 mg and for cases of hyperemesis 10.1 mg. The results obtained by De Wesselow and Wyatt (1924), by Nicholas, Johnson, and Johnston (1934), and by Labignette (1937) did not indicate any definite effect of eclampsia or nephritis on the calcium level. On the other hand, Laffont and Bourgaud (1936) obtained values of 7.6 and 7.8 mg in two cases of eclampsia.

#### INORGANIC PHOSPHORUS

According to Peters and van Slyke (1931) the inorganic phosphorus in healthy adults varies from 2.5 to 5.5 mg per 100 ml. Mull and Bill (1933) in their series of 207 healthy non-pregnant women of child-bearing age found that the range of values was 3.2 to 4.4 mg under 30 years and 2.6 to 4.2 mg over 30 years. The same authors (1934) in their series of 900 pregnant women found that the inorganic phosphorus reached an average minimum of 3.24 mg at the seventh month. This value is definitely higher than the average obtained in our series (2.74) and also higher than that obtained by Schwirthe (1936) (3.05) from sixteen German women between the fourth and seventh months of gestation. The same authors also found for thirty-three healthy non-pregnant women a mean of 3.3 mg. These data seem to suggest that higher values are to be obtained in American women than in European women, but the evidence is not enough to make any definite statement on the point. Mull and Bill (1934) found that the inorganic phosphorus level was affected by the season but that it was lowered by ingestion of food and by advancing age. In our series no evidence could be discerned of an effect of the season but the numbers were undoubtedly too small to draw any definite conclusion to be come to on this point. The amount of the fall found by Mull and Bill (1934) in pregnancy advanced was slight—from 3.53 mg at three and a half months to 3.24 mg at the seventh month on an average. A similar fall was observed by Meranze and Rothman (1937) between the first and

seventh months—namely 333 mg to 300 mg. The evidence therefore indicates that the serum inorganic phosphorus like calcium falls during gestation but apparently not so much as calcium.

De Wesselow and Wyatt (1924) state that the plasma inorganic phosphorus in the nephritic toxæmia or pre-eclampsia may be as high as 5 mg, but only one of the cases they cite bears this out. They point out, however, that inorganic phosphorus would only be definitely raised in grave cases of retention of excretory products.

Attention has been drawn in recent years to the significance of the product  $\text{Ca} \times \text{P}$  which is stated to be about 20 in health. Since both these blood constituents fall during gestation it follows that the product should be somewhat less than 20. The mean value of the product in our series is 25. In the series of Mull and Bill (1935) it averaged just over 31.

#### PHOSPHATASE VALUES

The range of phosphatase values in adults is given by Bodansky (1932-3, 1933) as 1 to 4 units. Meranze, Meranze and Rothman (1937) found that it rose throughout pregnancy from an average of 208 units at the third month to 479 units at the seventh and to 1033 units at the ninth in 201 subjects. The range of values was very wide especially in the later months, those at the third, seventh and ninth months being 164 to 304, 216 to 555 and 566 to 2448 respectively. The average of their series at the seventh month 479 units is distinctly higher than that obtained in our series 289 and their values are at a higher level than ours, their range at the seventh month being 216 to 555 compared with 10 to 50. These observers however used a modification of Robert's (1933) method which gives higher values numerically than Bodansky's so that the figures are not strictly comparable. Cayla and Fabre (1935) found a mean of 16 units (not Bodansky units) in five non-pregnant women aged 16 to 25 years and a mean of 30.8 in fifteen pregnant women between six and a half and nine months. The evidence therefore goes to show that pregnancy causes the phosphatase to rise steadily.

Inspection of the phosphatase values suggested that they were higher in those women who exhibited evidence of illness sufficient to cause some degree of incapacitation during these periods than in those who remained in good health. Unfortunately the number of subjects was too small the complaints too diverse, and the clinical information too incomplete to attempt to divide those whom we shall call "ill" for shortness into groups in accordance with the aetiology of their illnesses. Much as we dislike grouping patients with widely varying signs and symptoms such as those of toxæmia and puerperal pyrexia under one head the trend of values was too definite to be ignored. Accordingly the phosphatase values of all the "ill" subjects numbering fifty-two were averaged and the mean compared with the mean for the well subjects numbering forty-five. The ill group gave an average of 309 units per 100 ml and the well group one of 267. The difference 0.42 is slightly more than is likely to occur by chance the S.E. (standard error) of the difference being  $\pm 0.18$ . The distribution of values showed that six were below 2 units and nine above 4 units in the "ill" group compared with eight values below 2 units and one above 4 units in the well group. These results suggest that the difference between the two groups was real and also that the state of the metabolism of calcium and phosphorus was more satisfactory in the "well" group since a high phosphatase level is generally understood to indicate some disorganization in the

metabolism of these elements. Although we cannot attach any definite significance to these results we are nevertheless of the opinion that they should be recorded.

No definite relation could be discerned between the state of health of the subjects during pregnancy, labour or the puerperium and the concentrations of haemoglobin, calcium and phosphorus in the blood. The differences between the mean values for these constituents in the well and in the ill groups were found to be without statistical significance nor did the distribution of values reveal anything definite. Of the twenty-five subjects with haemoglobin below 70 per cent., ten were in the well group and fifteen were in the ill group—that is 22 per cent. and 29 per cent. of the respective categories. Of thirty-seven patients with calcium below 7 mg, sixteen belonged to the well and twenty-one to the ill group—that is 35 per cent. and 40 per cent. of the respective categories. In view of the fact that the differences between the means in the two groups are not statistically significant it is probable that little importance can be attached to them.

#### THE BACTERICIDAL TEST

Nineteen bloods were tested bacteriologically, and twenty failed to inhibit the growth of streptococci. Two of the subjects developed puerperal pyrexia according to the Public Health (Notification of Puerperal Fever and Puerperal Pyrexia) Regulations, 1926. The blood of one of these cases inhibited the growth of streptococci while the other failed to do so. The bactericidal action of the seventh month therefore did not give any indication of the susceptibility of the subjects to streptococcal infection during the puerperium. It must however be remembered that between the time of the test and the puerperium about three months elapsed during which the powers of resistance may have altered. Furthermore we do not know whether and to what extent other women than those who developed fever were exposed to infection.

It will be of interest to give some further details of the two cases of pyrexia. One of these was diagnosed as genuine puerperal pyrexia and the cause of the fever in the other case was attributed to mastitis. In the case of true puerperal pyrexia labour was normal but on the third day afterwards the temperature rose rapidly to 102 F, falling again to normal on the fifth day. During pregnancy this patient had had sciatic pains and a vaginal discharge and had been ill with influenza two weeks before confinement. The blood picture at the seventh month was haemoglobin 56 per cent, calcium 9.2 mg, inorganic phosphorus 2.6 mg and phosphatase 29 units per 100 ml. The blood inhibited the growth of streptococci. In the other case the temperature reached 102 F on the fifteenth day and 100 F on the sixteenth. The right breast was red and painful but the inflammation rapidly yielded to conservative treatment and the patient was normal on the nineteenth day after labour. During pregnancy there was a persistent mitral systolic murmur but no other signs or symptoms of illness. The blood picture at the seventh month was haemoglobin 87 per cent, calcium 11.3 mg, inorganic phosphorus 2.3 mg and phosphatase 25.4 units per 100 ml. The blood failed to inhibit the growth of streptococci. There was therefore nothing noteworthy in the blood findings of either subject.

#### Summary

The haemoglobin and bactericidal power of the blood against haemolytic streptococci and the calcium, inorganic phosphorus and phosphatase contents of the serum were

determined in 101 women at the seventh month of pregnancy attending ante-natal clinics in Blackburn.

In the series seven women out of ninety-five tested (7 per cent) were considered to be definitely anæmic, and eighteen (19 per cent) probably slightly so. In thirty-seven out of ninety-six tested (39 per cent) the calcium level was less than 9 mg per 100 ml, which is believed to be abnormally low. The product calcium  $\times$  phosphorus was 25 on the average. The blood of twenty-two women out of ninety-nine tested (22 per cent) failed to inhibit the growth of streptococci, and of these, one developed pyrexia during the puerperium, fever also occurred during the puerperium in a patient whose blood inhibited growth at the seventh month. A review of the literature indicates that the serum calcium and phosphorus fall and the serum phosphatase rises gradually as gestation advances.

In addition to the several individuals mentioned in the text who co-operated in this research and to whom our thanks are due we also wish to express our gratitude to the following: Dr D. W. Auchincloss for assistance and advice in biochemical methods; Dr A. Bradford Hill for assistance and advice in statistical analysis; Professors Dible and McLeod, for advice on bacteriological methods; and Dr Colebrook, for supplying the culture of hæmolytic streptococci.

## CHANGES IN BLOOD PRESSURE AND RESPIRATORY VOLUME FOLLOWING A SPINAL ANAESTHETIC

BY

D. LINCOLN LEWIS, F.R.C.S.

AND

E. G. M. PALSER, M.B.

There is always a fall of blood pressure following the administration of a spinal anaesthetic. This has been attributed to (1) vasomotor paralysis of the legs and trunk, causing vasodilatation and loss of blood in effective circulation, and (2) diminution of respiratory excursion due to intercostal paralysis causing a decline in negative intrathoracic pressure during inspiration and a decrease of the venous return to the heart. The occurrence of a fall in respiratory volume has been ascribed to abdominal and intercostal paralysis and to medullary anaemia following the fall in blood pressure.

Observations on the changes in systolic and diastolic blood pressure and in respiratory volume after the administration of a spinal anaesthetic were carried out in twenty-three cases, using the following technique: the anaesthetic was crystalline novocain, in amounts varying between 0.100 and 0.150 grammes (average 0.126 grammes) in solution in cerebrospinal fluid (average 1.88 ccm) injected fairly slowly (four seconds) into the third lumbar space. This anaesthetic is completely absorbed in five to ten minutes by the spinal nerves near the site of injection, thus there are no secondary changes due to spread of the anaesthetic to higher regions during the progress of the operation. Repeated observations, commencing four to ten minutes before injection of the anaesthetic, were made of brachial systolic and diastolic blood pressure and also of the volume of expired air. For the latter purpose a simple airtight mask of chloroplast was devised, adherent to the patient's face and attached to the valve apparatus of a nitrous oxide apparatus, which was in turn connected to a meter, read every two minutes. The following readings obtained by these methods give some information on the relation of the fall in blood pressure to the changes in respiratory volume.

### Relation of Blood pressure Fall to Respiratory Changes

It was found that there is a sharp fall amounting on an average to 40 per cent of the initial systolic and 36 per cent of the initial diastolic blood pressure, the mean time of onset being 2.6 and 2.2 minutes after the administration of the spinal anaesthetic. The variation in this fall in blood pressure, considered as a percentage of the original value, while not very great, is proportional to the level of anaesthesia attained. The average level was up to the seventh rib, the highest and lowest being up to the third and tenth ribs respectively. There is also a fall in respiration, which occurs on an average one minute later than the fall in blood pressure (in two cases slightly before, in two cases synchronously, and in nine cases after). This decline amounts to 41 per cent of the initial respiratory volume. These falls are regular, with a tendency to be biphasic in the case of blood pressure and a similar less pronounced tendency in the case of respiration. The fall ceases after 13, 12½, and 13½ minutes in the cases of systolic and diastolic blood pressure and respiration respectively. There follows a recovery of systolic and diastolic blood pressure and

The Council of the Royal Society of Arts gives notice that the next award of the Swinney Prize will be made in January, 1939 the ninety-fifth anniversary of the testator's death. Dr Swinney died in 1844, and in his will he left a sum of money to the Royal Society of Arts for the purpose of presenting a prize, on every fifth anniversary of his death, to the author of the best published work on jurisprudence. The prize is a cup of a value of £100, and money to the same amount. The award is made by a joint committee of the Royal Society of Arts and the Royal College of Physicians of London which appoints special adjudicators. The prize is offered alternately for medical and general jurisprudence, but if at any time the committee is unable to find a work of sufficient merit in the class whose turn it is to receive the award, it is at liberty to recommend a book belonging to the other class. On the last occasion (1934) the prize was awarded for general jurisprudence. It will, therefore, be offered on the present occasion for medical jurisprudence. Any person desiring to submit a work in competition or to recommend any work for the consideration of the judges should do so by letter, addressed to the Secretary of the Royal Society of Arts, John Street, Adelphi, London, W.C.2, not later than November 30, 1938.

respiration of  $7\frac{1}{2}$ ,  $10\frac{1}{2}$  and 14 per cent of their initial values respectively which occupies about eight minutes.

It would appear from these observations that the fall in blood pressure is at least in part independent of changes in respiratory volume. It was found that if the respiration volume was maintained at the initial level—for example by CO inhalation—the decrease in blood pressure occurs but it takes longer (average eighteen minutes) and is more markedly biphasic. Recovery of blood pressure follows as before.

The effect of maintaining respiration was subsequently demonstrated by the induction of hyperpnoea by CO inhalation. If a flow of  $1\frac{1}{2}$  litre per minute is administered (of which about  $1\frac{1}{4}$  litre per minute is inhaled) respiration is increased by about 45 per cent of its initial volume, the rise being regular and rapid of almost instantaneous

64 per cent and 6 per cent of their initial values. The suggestion that medullary anaemia is the cause of the fall in respiratory volume is not borne out by the findings that the Trendelenburg position while raising the brachial and to a greater extent the cranial blood pressure does not result in an increase of respiratory volume.

It was noted that in cases of hypertension with arteriosclerosis the initial high systolic blood pressure fell very rapidly, the fall being a greater percentage of the initial blood pressure and the final blood pressure being as low as or lower than in normal cases. In these cases the Trendelenburg position has the effect described above bringing the blood pressure up to about the normal low level. Subsequent induction of hyperpnoea by CO inhalation has less than the usual effect in raising blood pressure. This increased decompensation occurring in cases of hypertension is shown by comparing the initial systolic blood pressure with the initial and final values of the function  $S'2D-20$ . On an

CHART 1

CHART 2

CHART 3

CHART 1—Average variation of blood pressure and respiration following the administration of a spinal anaesthetic

CHART 2—Variation of blood pressure and respiration following the administration of a spinal anaesthetic in a case of hyperpnoea

CHART 3—Variation of blood pressure and respiration following the administration of a spinal anaesthetic in a case with normal initial blood pressure

onset and attaining its maximum in three to four minutes. About 36 minutes after the beginning of CO inhalation there is a rise (completed in another four minutes) of  $3\frac{1}{2}$  per cent and 5 per cent of the initial systolic and diastolic blood pressure. At the same time the radial pulse volume is appreciably increased.

These effects of either maintaining or subsequently raising the respiratory volume suggest that there is a relation between the maintenance of respiratory volume and the blood pressure but also that another result of administering a spinal anaesthetic is independent of respiration and much more potent in causing a fall of blood pressure and that of the total fall in blood pressure only a small percentage can be counteracted by maintaining a normal or hypernormal respiratory volume.

The result of loss of blood in effective circulation was shown by placing the patient in the partial Trendelenburg position the feet being raised not more than one foot above the level of the head. This brings about an immediate rise in systolic and diastolic blood pressure of

average in those cases whose initial blood pressure was 130 mm Hg or below decompensation is slight while in those cases in which initial blood pressure was in the neighbourhood of 180 mm Hg decompensation amounts to a 25 per cent decrease in the initial and final values of  $S'2D-20$ . The abnormally low blood pressure in these cases will however respond to some extent to ephedrine. The majority of the subjects of these observations had received premedication with  $1\frac{1}{4}$  grain of morphine and  $1\frac{1}{150}$  grain of hyoscine.

The cause of the biphasic type of fall of blood pressure is not clear. It might be suggested that this temporary check in fall of blood pressure may indicate the normal compensation to lowered blood pressure by contraction of the spleen, visceral ischaemia, etc. The observations demonstrate that CO is of immediate assistance during the administration of a spinal anaesthetic as well as for prophylaxis against post-operative pulmonary collapse. The diagrams show the average response of the twenty-three cases to the various conditions imposed upon them.

and the response of a typical case of hypertension and of a case with normal blood pressure

### Conclusions

- 1 The greater part of the fall in blood pressure is due to vasomotor paralysis
- 2 A minor cause is the diminished respiratory excursion, which is due to abdominal and intercostal paralysis rather than medullary ischaemia
- 3 The Trendelenburg position has an immediate definite effect in increasing the blood pressure but not the respiratory volume
- 4 The induction of hyperpnocia has a small delayed effect in increasing the blood pressure

## A BRIEF REVIEW OF 426 CONSECUTIVE CASES OF URINARY CALCULUS

BY

H. P. WINSBURY-WHITE, F.R.C.S.

*Surgeon St Paul's Hospital Urologist St John's Hospital  
Lewisham Urologist Princess Elizabeth of York  
Hospital for Children Shadwell*

The investigation of a large number of cases of a disease such as lithiasis, chiefly because of the wide distribution of that condition throughout the urinary tract, reveals some interesting data. First of all is the fact that the male is invariably more prone to urinary lithiasis than the female: there are approximately two cases in the former to every one in the latter. My figures are as follows: male, 278, female, 148. Letts (1936) figures from the London Hospital are in the same proportion; these cover the period 1905-34. The next important fact to note is the high proportion of cases which occur in the upper urinary tract (79 per cent) in comparison with the lower. The London Hospital figures (74 per cent) are not far removed from mine on this point. The following table shows the general distribution throughout the urinary tract in my cases:

Kidney, 220	}	337 = 79.10% upper urinary tract
Ureter, 117		
Bladder, 80	}	89 = 20.90% lower urinary tract
Urethra, 9		
426		

### Staphylococcal Foci of Infection in Renal Calculus

Several Continental writers, notably Hellstrom (1936) of Stockholm and Hryntschak (1935) of Vienna, have called attention to the importance of chronic staphylococcal foci of infection as predisposing factors in the aetiology of renal calculus. Hellstrom found the staphylococcus in the structure of the stones in a large number of his cases. At the same time he has identified chronic infective foci in the genitalia of many of his patients. In 115 cases of stone in the upper urinary tract which I have examined in the same way I observed similar foci in 72 per cent. These were noted in the prostate, seminal vesicles, urethra, epididymides, the cervix uteri, and at the bladder neck. The importance of treating such foci is obvious, particularly in the hope of removing a cause for further stone formation. One other aetiological factor I found important in this series—namely, a dilatation in the urinary tract which pre-existed the calculus. This was noted in

15 per cent of my cases, and had its maximum incidence among children, concerning whom the dilatation appeared to be the principal aetiological factor with regard to stone. Parathyroid or deficiency disease, diseases of the bone, excess of vitamin D, and hypercilemia from various causes are all known to encourage stone formation, but they have certainly played an insignificant part in the cases forming the subject of this article.

### Age Incidence

The average age incidence in 220 cases of renal calculus was 39.5 and in 117 cases of stone in the ureter 39.7. The disease is slightly more common on the left side than on the right. The percentage figures of my cases are as follows: left, 50.55, right, 36.40, bilateral, 13.05. In the kidney, calculus is of equal incidence in both sexes.

When we come to consider the ureter, however, there is a remarkable change in the sex incidence. Indeed, ureteric calculus is about twice as common in the male as in the female: eighty-two of my cases were in males and thirty-five in females. The London Hospital figures are roughly in the same proportion. Here is offered an opportunity for an interesting speculation as to anatomical differences, which might supply the explanation. When we come to vesical calculus there is a still greater disparity in the sex incidence, the male greatly predominating, actually to over 90 per cent. There is nothing new about this relationship, it being practically the same as in ancient times.

### Recurrence and Mortality of Renal Calculus

I have no figures to put forward at present as to recurrence of renal calculus following operations on the kidney for stone. The literature offers a wide range of results according, I should imagine, to the way the investigations have been conducted. Although I have not yet undertaken a systematic investigation on this matter I have come across a few of my patients who have had a recurrence. In some cases this occurred in the kidney from which stone was removed, in others the stone has subsequently appeared for the first time in the opposite organ. With regard to the latter group, I would like to emphasize the fact that, in those cases in which after full investigation I have thought it proper to do nephrectomy, I have no knowledge of any in which stone has ultimately appeared in the remaining kidney. I call attention to this matter because I am of the opinion that when a kidney which is badly damaged by stone is left behind it is likely to encourage the formation of stone on the opposite side. The percentage of recurrence is quoted by some authorities as being no more than two to three after nephrectomy. My mortality for operations for renal calculus in 135 cases is 2.9 per cent.

### Stone in the Ureter

Treatment of stone in the ureter presents an interesting problem. The outstanding fact about these cases is that the great majority of stones pass spontaneously without any assistance. This was so in 67 per cent of the cases that I was able to trace. If the stones do not pass in due course they can usually be made to do so by some minor measures carried out through the cystoscope, such as passing ureteric catheters and slitting the ureteric orifice. Sometimes several weeks elapse between the instrumentation and the passage of the stone. The longest interval in my cases was nine months. As a rule there is no appreciable damage to the renal function from the lodgment of a small stone in the pelvic portion of the

water for such a period. But regular observation must be kept by plain x-ray and intravenous urography. Out of a total of 117 cases of stone in the ureter only 23 per cent required open operation. In 26 per cent of these cases the kidney was so badly damaged that it had to be removed and in all but one of them nephro-ureterectomy rather than a simple nephrectomy was performed. In 17 per cent trans-urethral instrumentation was carried out to assist the passage of the stone. There was no mortality from any form of operation on the ureter.

### Change in Incidence of Urinary Lithiasis

When one considers the published statistics of hospital records of urinary lithiasis up to fifty years ago it at once becomes obvious that a remarkable change has since occurred in the incidence of this disease. For before this time urinary lithiasis was largely a matter of vesical calculus—it was one of the commonest of hospital diseases to-day in this form it is one of the most uncommon. Moreover vesical calculus in those earlier times had by far its highest incidence among the children of the working classes. It did not occur at all in children of the well-to-do. So that it becomes an interesting question to ask why this form of the complaint has so completely disappeared. The explanation is of course simple—namely that in bygone days this form of urinary lithiasis was one of the many manifestations of faulty feeding, which as conclusively shown by modern experimental work, is largely a matter of deficiency of vitamin A of an animal origin and to a less extent of wholemeal bread (McCarrison 1931) the latter being harmful only when it is not modified by adding other dietetic ingredients. On looking back one can see how the improved standard of living among the working classes as time has progressed has made milk and butter more accessible to them and how the improvement in the milling of wheat has eliminated the bread factor.

It is abundantly clear that urinary lithiasis which manifests itself as a deficiency disease is vesical rather than renal and bladder stone is still very common in those countries where the predisposing conditions exist. Vesical calculus in our own midst to-day is almost invariably associated with bladder neck obstruction of one kind or another and is commonest in men past middle life, the average age of my patients was 52.6 years. Thus an important question of treatment is involved. To crush a stone and leave the obstruction is to invite recurrence of the calculus. Prostatectomy is indicated in some cases and transurethral resection of the bladder neck in others.

Now we come to another remarkable contrast—namely that renal calculus was nothing like so common as it is to-day. Even the absence of means of diagnosis by x-rays fails to explain the obvious increase in this form of lithiasis. Thus while we are aware of the disappearance of vesical calculus in the young for which we have a ready explanation, we are equally aware of an increase in upper urinary tract lithiasis the maximum incidence of which has moved to the fourth decade and the reason for which is obscure. Let's London Hospital figures leave no doubt about the change that has occurred in relation to the kidneys by comparing the 1915-24 decade with the succeeding ten years, it is seen that an increase of nearly 50 per cent took place in the stone cases admitted to hospital in the latter period. The incidence was predominantly in the upper urinary tract. Reports from Germany (Grossmann 1933) show that the increase of renal calculus is also general in that part of the world—at least in Central

Europe and in some adjacent localities. A queer fact which has come to light with respect to this wave of urinary lithiasis is that it seems to have begun somewhere about 1924. In some localities the increase has been as much as 1000 per cent. No adequate explanation of this phenomenon has so far been forthcoming. It is difficult to believe that dietetic hardships suffered during the war are responsible for an increase at such a distant date.

### Vesical and Urethral Calculus

With regard to the treatment of vesical calculus whereas litholapaxy is commonly looked upon as being the proper method I consider it inexpedient to carry this out in quite a large number of cases—actually 45 per cent of seven cases—the reason being that often there was an obstructive condition at the bladder neck requiring surgical intervention. For example in several cases I performed transurethral resection of a fibrous bladder neck obstruction either at the time of or subsequent to litholapaxy. There was a mortality from suprapubic lithotomy of 50 per cent. Of the vesical calculus cases 51 per cent were treated by litholapaxy with a mortality of 4.8 per cent.

Urethral calculus which as one would expect is predominant in the male is the least common of the types of lithiasis with regard to locality. It has the special feature that a large proportion of the cases are associated with lithiasis elsewhere in the urinary tract—in my cases 62 per cent. In other words such stones generally migrate from higher levels. Of my cases 55 per cent were in the prostatic urethra, the others being almost equally distributed in the different parts of the anterior urethra. The methods of removal varied according to the cases, several were treated by external urethrotomy, one prostatic case by suprapubic lithotomy and another by pushing the stone into the bladder with a sound and then crushing it. In one female case a large stone was visible at the external urinary meatus through which it was removed with forceps. There was no mortality from the urethral cases.

The Swedish Hospital for Radium Treatment has lately moved into modern premises erected close to the new Carolina Hospital in Stockholm. The Radiumhemmet, as the hospital is called, was established with the aid of the funds subscribed by the Swedish people as a gift to King Gustaf on his seventieth birthday ten years ago. Every technical resource has been utilized to make this clinic up to date. It has five rooms for radium treatment and a number of wards for three or six patients. The radium is stored in special safes which are inspected every morning. To protect the staff from dangerous radium rays rigorous safety measures have been introduced. When taking out the radium tubes from the safes the nurses are protected by lead screens 4 in. thick and the tubes are conveyed between departments in heavy wagons on rubber wheels. In the basement is the department for telerradium treatment, the walls are built of iron ore concrete 4 ft. 6 in. thick to prevent the rays from penetrating them. There is also a special x-ray department. The clinic has 100 public and 13 private beds and there are 150 physicians, nurses and other officials. Everyone employed in the handling of radium or x-ray apparatus is given long holidays.

# THE BRAGG-PAUL PULSATOR IN TREATMENT OF RESPIRATORY PARALYSIS\*

## REPORT ON THIRTY-FOUR CASES

BY

C. J. McSWEENEY, M.D., F.R.C.P.I., D.P.H.

Respiratory paralysis following diphtheria is a comparatively rare condition, but it is not uncommon when diphtheria of a virulent form is prevalent. Among roughly 3,000 cases of diphtheria treated in recent years thirty-three authentic instances of respiratory paralysis have occurred in Cork Street Hospital. In all cases the involvement of the diaphragm, with or without the intercostals, was part of a widespread post-diphtheritic paralysis. A pre-existing palatal and pharyngeal paralysis was invariable, and in a majority of cases some other paralysis was present as well—for example, ciliary, external rectus, neck muscles, facial muscles, etc. Most commonly the involvement of the respiratory muscles occurred at the end of the sixth or during the seventh week. The onset of the paralysis was most often gradual, but in a few instances sudden arrest of respiration occurred, with alarming symptoms of defective pulmonary aeration. Respiratory paralysis was met with only in those cases of severe nasopharyngeal diphtheria which, in the early stages of the disease, had bull necks and severe toxæmia. There were, however, three cases of "missed diphtheria" admitted to hospital, respectively on the fourteenth, thirty-first, and forty-second day of the disease, with post-diphtheritic paralysis, and in these cases one can only assume the extent of the throat lesions, which had cleared by the time the children were admitted to hospital. One other case of respiratory paralysis is included in this series, the cause here being a spreading anterior poliomyelitis.

### The Apparatus

Since October, 1935, every case of respiratory paralysis has been treated in the Bragg-Paul pulsator—an apparatus designed by Mr. R. W. Paul at the suggestion of Sir William Bragg. The original apparatus was shown by me to the Dublin Biological Club in October, 1935, and was demonstrated by Dr. Kerridge of the Department of Physiology of the University of London at the Annual B.M.A. Meeting in Oxford in 1936. Briefly, the apparatus consists of a distensible rubber bag applied around the patient's chest in the form of a belt, this belt being rhythmically filled with, and emptied of, air from a bellows, which in turn is compressed and relaxed by a moving plate, operated electrically. There is a gauge to indicate the amount of pressure applied to the chest, and the rate of compression can be modified to suit the respiratory rate of the patient—18, 20, or 22 strokes per minute, as the case may be. The pressure in the chest belt is controlled by an escape valve fixed to the bellows, and by opening this valve to a greater or less extent the pressure can be reduced or raised. With the original apparatus pressures of 0 to 25 mm. Hg give completely satisfactory results for children of 4 or 5 years of age, but the one adult patient treated required 10 to 35 mm. Hg.

### Results of its Use

Up to date thirty-four cases have been treated in the apparatus, and of these twenty-six made uneventful recoveries. One of the eight fatalities had been treated in the apparatus for four days when the machine broke

down, and before a new part could be made the patient died. The remaining seven patients died of causes other than respiratory failure—six of them from late cardio-vascular failure, and one from gangrene a fortnight after coming out of the pulsator and sixty-one days from the onset of his diphtheria. Of the twenty-six cases treated successfully it will be sufficient perhaps to give one or two illustrative examples. All the cases conformed to this type, and to include others would be waste of time.

### Illustrative Cases

*Case No. 390/37*—A boy aged 6 with very toxic naso-pharyngeal ('gravis') diphtheria and marked hæmorrhagic extravasations into skin. Admitted on the fourth day, palatal paresis occurred on the eleventh, paralysis of the neck muscles on the twenty-fifth, pharyngeal paralysis on the thirty-first, and complete diaphragmatic paralysis on the thirty-eighth, put in pulsator. Full recovery of the diaphragm was very slow and because of sluggish shallow respirations the pulsator was kept on until the fifty-sixth day when the respiratory muscles were found to be completely recovered. All other paralysis cleared up about the same time, and subsequent recovery was uneventful.

*Case No. 770/37*—A boy aged 5 with very toxic faucal diphtheria of the 'gravis' type and considerable skin hæmorrhages. Admitted on the alleged second day. Palatal paresis occurred on the seventh day, early cardiovascular failure on the eighth with vomiting, precordial pain going on to gallop rhythm on the fifteenth, paralysis of the neck muscles on the twenty-fifth, pharyngeal paralysis on the thirty-sixth, and sudden arrest of respiratory muscles on the fortieth day, put in pulsator. There was ptosis of the left eyelid on the forty-second day and the respiratory muscles were functioning normally on the forty-fifth. The pulsator was now discontinued. Left internal strabismus was observed on the fifty-first day. The pharyngeal paralysis cleared up on the fifty-fourth, the neck muscles on the sixty-ninth, and the strabismus on the seventieth. Subsequent recovery was uneventful.

I ought to add that there was no interference with the routine management, nursing, and treatment of patients, all of whom were nicely fed for a coexistent pharyngeal paralysis while receiving artificial respiration. Most of the patients were quite young children, but none raised the slightest objection to treatment in the apparatus. They slept normally while undergoing artificial respiration, and the other occupants of the ward did not object to the operation of the pulsator. There can be no doubt that this simple but ingenious apparatus marks a great advance in the treatment of a sequel of diphtheria which has been hitherto almost invariably fatal. The patient with anterior poliomyelitis behaved in an exactly similar manner to the diphtheritic cases when put in the pulsator. On two occasions two children developed respiratory paralysis about the same time, and in this emergency the escape valve was connected to another belt by means of a length of hose-pipe and suitable fittings, and by this makeshift arrangement we were able to maintain artificial respiration successfully in the second child without disturbing the one already under treatment. All four children eventually recovered.

The apparatus has also been employed at the Richmond Hospital, Dublin, and I am informed by Mr. A. McConnell, F.R.C.S.I., that recently it saved life by restarting respiration in at least two of his patients during the course of prolonged brain operations.

### Improvements

During the last twelve months I have been in constant touch with the original designer of this apparatus, Mr. R. W. Paul, and have kept him advised as to certain minor troubles we have experienced with the pulsator. The chief

\* A communication to the Section of Medicine, Royal Academy of Medicine in Ireland, March 18, 1938.

of these was the sucking in of the bellows with consequent chafing, necessitating frequent repair of punctures and eventually replacement of the bellows. Mr Paul has entirely got over this difficulty by providing for a shorter length of stroke ( $2\frac{1}{2}$  inches instead of 3 inches) and certain other modifications have also been incorporated to ensure almost noiseless working of the apparatus. One other improvement is the inclusion of a two way connection which readily allows two children to be treated in the apparatus simultaneously—a direct development of the improvised arrangement we made in Cork Street two years ago. Another important improvement in the belt is the addition of shoulder straps which will prevent the belt from slipping down over the abdomen, an eventuality that had to be constantly watched for with the older belts. The fastening of the new belt is by means of a chain clip which is also an improvement on the older buckles.

### Conclusion

The Bragg Paul pulsator is an efficient artificial respirator which is specially adapted to the treatment of post diphtheritic respiratory paralysis or respiratory paralysis due to anterior poliomyelitis. It is also of use in restarting respiration which may be reflexly stopped during the operation of tracheotomy or during any operation where such reflex stoppage may be anticipated. It has been used too to re-expand a lung and cause healing of a chronically discharging empyema. The new model is a more compact and a neater apparatus than the original and promises to have even greater efficiency as an artificial respirator.

## TRANSFUSION WITH STORED BLOOD

BY

T. I. WILSON, M.B., F.R.C.S. Ed.

Clinical Tutor, Royal Infirmary, Edinburgh

AND

J. M. M. JAMIESON, M.B., Ch.B.

Late House Surgeon, Royal Infirmary, Edinburgh

Transfusion with stored blood has been practised for many years and during the great war it was used particularly in the front line hospitals of certain Dominion medical units. Thereafter the practice appears to have fallen into disuse but was revived again more recently by Russian surgeons who use blood taken from the cadaver within a few hours of death. It is also recorded that certain supplies of stored blood have proved of great value in the course of the present civil war in Spain.

This paper contains details of fourteen cases of blood transfusion exemplifying the value of having a supply of blood in cold storage ready for immediate use. The field of investigation has been purely a clinical one and observations have been limited to the general reaction of the patient to the treatment carried out. The indications for transfusion in the cases here recorded are for the most part weakness and anaemia associated with sepsis and malignant disease rather than the replacement of blood loss by haemorrhage which was present in only three instances.

### The Source of Supply

The source of supply has varied: two patients with polycythaemia were generous donors and in the other cases the blood was obtained from healthy individuals.

In all except one case the blood was Group IV in type and in each instance the citrate method was employed the concentration of sodium citrate being 0.38 per cent in the stored blood.

### Technique

The blood is withdrawn from the donor's cubital veins under strict aseptic conditions and is collected in sterilized flask containing the required amount of sodium citrate solution for the quantity of blood withdrawn. A pint of blood is thus collected in each flask which is closed with a sterile plug of gauze and wool and then sealed and labelled. This supply is stored at once in a refrigerator at a temperature of  $-10$  to  $-3$  C. In our series of cases the stored blood has been used after a period of from four to thirty eight days.

Serological tests are carried out upon all donors and before use the patient's serum is typed directly against the corpuscles of the stored blood. On examining the stored blood microscopically even as late as five weeks from the time when it was originally put on ice the erythrocytes were observed to be normal in appearance in every way except for a few which showed crenation. During storage sedimentation of course occurs and before use the flask is gently agitated to mix the cells again with the plasma. The method wherein sterile glass balls are placed in the flask to promote more thorough mixing we do not favour as this tends to break down many of the cells.

After mixing the blood thoroughly it is decanted into a sterile measure through a filter composed of layers of gauze. This filter is necessary because late clotting tends to occur in citrated blood in certain cases and clots must of course be eliminated. The blood is infused into the recipient's circulation through a vein in the arm by means of a tunnel tube and glass cannula. It is given unheated the reason being that heat would appear to cause an alteration possibly of the protein content and toxic symptoms may follow the administration of blood so treated. Our practice is to give the blood after it has stood at room temperature for a period of from half to one hour. The flask is then still cold to the touch. In the cases reported below only two were followed by a reaction and in these the blood had been heated to normal temperature. It is significant in this connexion that we have observed reactions follow immediate transfusions in cases where the flask of blood has been placed in warm water.

The second precaution to be taken in administering blood is to ensure that the rate of flow is even and slow. We endeavour to occupy a period of about fifty minutes in giving one pint of blood this representing a quantity of just over 10 ccm per minute. This rate of flow is frequently diminished by spasm of the vessel induced by the cold blood.

### Case Records

*Case 1*—A man aged 49 suffering from carcinoma of the colon with perineoplastic abscess was admitted with acute obstruction. Colostomy was performed and later resection. The first transfusion one pint of Group IV blood five days old was given on October 15 1936 and a second transfusion of one pint of Group IV blood twenty one days old was administered on December 7. There were no reactions and the patient is now alive and well.

*Case 2*—A man aged 50 with carcinoma of the urinary bladder. The ureters were transplanted into the colon and total cystectomy was performed. The first transfusion given on October 18 1936 was one pint of Group IV blood eight days old the second transfusion on November 13 was half

a pint of Group IV blood seven days old. No reactions occurred.

**Case 3**—A man aged 42, admitted with congenital polycystic disease of the kidneys and protuberant haemorrhage. The first transfusion on November 30, 1936, consisted of half a pint of Group IV blood twenty-four days old. The second transfusion on December 9 was of one pint of Group IV blood ten days old. The first transfusion was followed by a transient reaction of the "rigor" type but there was a marked reduction in the haematuria. The blood used in this transfusion had been heated to 'normal' temperature. Nephrectomy had to be performed, however, and the blood loss was made good by the second transfusion. The patient is now alive and well.

**Case 4**—A man aged 47 with perforated duodenal ulcer treated on admission by simple closure. Haematemesis occurred on the same evening. On December 11, 1936, half a pint of Group IV blood four days old was transfused. The patient had no immediate reaction but bleeding recurred and he died.

**Case 5**—A woman aged 49 suffering from chronic cholecystitis with acute cholangitis and abscesses. Cholecystectomy was performed on January 17, 1937. The first transfusion (January 16, 1937) was of three quarters of a pint of Group IV blood twenty-two days old. The second transfusion (January 17) was of half a pint of Group IV blood twenty-three days old. There was no immediate reaction and the patient's condition was much improved after the post-operative transfusion. Her myocardium failed, however, and she died on the following day.

**Case 6**—A man aged 30. This was a case of subphrenic abscess in a patient with spastic diplegia. The transfusion (February 24, 1937) was of one pint of Group IV blood ten days old. No reaction occurred, and the patient is now alive and well.

**Case 7**—A man aged 68 with renal adenocarcinoma. Nephrectomy was performed, and a large tumour was dealt with. Transfusion (January 20, 1937) consisted of half a pint of Group IV blood thirty-eight days old. No reaction occurred. There was a definite improvement in the patient's general condition, but hypostatic pneumonia developed and death took place seven days later.

**Case 8**—A man aged 60 with suppurative tenosynovitis and septicaemia. The patient was very ill. Transfusion (February 28, 1937) consisted of one pint of Group IV blood twenty-eight days old. This produced a definite general improvement, there were no reactions. The condition became progressive, however, and death occurred with pyaemia and multiple abscesses, sixteen days later.

**Case 9**—A woman aged 64 with carcinoma of the urinary bladder. The ureters were transplanted into the colon. A transfusion of one pint of Group II blood five days old was given on June 13, 1937. The patient showed marked improvement at the time but died three weeks later from bronchopneumonia.

**Case 10**—A woman aged 24. This was a case of secondary haemorrhage in acute puerperal mastitis. Half a pint of Group IV blood thirty-five days old was transfused on June 27, 1937. A slight reaction of "rigor" type followed but satisfactory progress was obtained thereafter. The patient is now alive and well. The blood in this case was heated to 'normal' temperature.

### Results

It will be seen that these ten patients had between them fourteen transfusions. Two deaths occurred in the period immediately following transfusion, one from syncope and the other from recurrence of haemorrhage. In three other cases the outcome was eventually a fatal one. None of these cases showed any reaction in the immediate post-transfusion period, and in no case could the fatal result be attributed, in any degree, to the administration of stored blood.

Five of the patients—comprising eight transfusions—are alive to-day, and among these are the two cases in which reactions occurred.

### Summary

- 1 Fourteen instances of delayed transfusion with stored blood are recorded.
- 2 The technique and method of storage are described.
- 3 The precautions to be observed are instanced.
- 4 The safety of the practice is demonstrated.

We desire to express our thanks to Mr. Henry Wade, in whose wards these cases were treated for his permission to publish these records. We are further indebted to Mr. Wade and to Sir David Wilkie for their interest and help.

## Clinical Memoranda

### Spontaneous Cerebrospinal Rhinorrhoea

Escape of cerebrospinal fluid from a nostril is a rare condition. A review of the literature revealed only sixty-six cases reported up to 1934, and of these many were secondary to definite cerebral conditions.

**Aetiology**—Excluding fractures of the base of the skull, where the cause is obvious, and long-standing cases of increased intracranial pressure, either from tumour or from hydrocephalus without tumour, the cause of spontaneous cerebrospinal rhinorrhoea has not been clearly established. This is due to the fact that necropsy was performed on a limited number of cases only. In some of these the post-mortem findings were entirely negative, while in others the picture was masked by secondary infection. A tiny opening, however, was reported to have been found in the cribriform plate, and the prevailing theory attributes the condition to a congenital defect in the base of the skull—namely, a "cranio-pharyngeal canal" which is forced open by slight trauma or violent coughing or sneezing. McDougal thinks that the cerebrospinal fluid tracks down the perineural sheaths of the olfactory nerves.

**Symptoms**—The patient complains of a continuous watery discharge from one nostril. The flow is persistent, but may be altered by the position of the head, being increased when the head is bent forward and diminished in the upright position. On lying down it is swallowed. The fluid can be seen to come down from the upper pole of the nasal cavity between the septum and the middle turbinal.

**Diagnosis**—This is established by complete examination of the fluid, which should have the same composition as cerebrospinal fluid. Constantine introduced a solution of fluorescein by lumbar puncture, which appeared one and a half hours later in the fluid from the nose. Lumbar puncture, a procedure not without danger, should be done with a fine needle, and very little fluid drawn.

**Prognosis**—Unfortunately in the majority of cases no record the outcome of this condition is not stated. Many cases proved fatal as a result of intervention. In some cases, as in that reported below, the flow ceased spontaneously with rest in bed. Recurrence of the symptoms may take place many years later.

**Treatment**—As spontaneous cessation of the flow may occur with expectant treatment absolute rest in bed should be tried in all cases that are without apparent cause. If this fails, or in cases of recurrence of the leakage, a cranial operation must be advised. This consists in

exposing the region of the olfactory groove securing the surrounding dura and placing upon it a fragment of fresh muscle which occludes the opening. Spraying or local applications are useless and dangerous.

## REPORT OF CASE

A male Hindu aged 26 consulted me for a cold in the head early in January 1937. He complained of a continuous flow of clear fluid from his right nostril of three weeks duration. He stated that his pillow became soaked during the night with fluid and when in the supine position he felt it trickle down his throat. It was slightly salt in taste. On bending his head forward there was a constant dripping of a clear fluid that filled an ordinary test tube in about twenty minutes. His past history revealed a head injury sixteen years previously with unconsciousness for half an hour followed by complete recovery. In reply to leading questions the patient admitted that a week before the onset of his symptoms he accidentally received a blow on his chin from his brother's elbow. This caused some pain in his temples. He otherwise felt quite well except for insomnia from worry and some loss of weight.

Routine physical examination and complete examination by a neurologist revealed nothing abnormal. The fluid was seen to come down from the upper pole of the nasal cavity. A blood count showed a moderate anaemia with alteration in the size and shape of the red cells and a low haemoglobin content. A ray examination of the skull and a blood Wassermann test were negative. A lumbar puncture caused temporary cessation of the flow from the nose. Both fluids were colourless and the laboratory reports on them were as follows:

	CSF	Fluid from Nose
Wassermann	Negative	Negative
Glucose	No trace	Slight excess
Protein	725 mg. per 100 ccm.	75 mg. per 100 ccm.
Serum	40 mg. per 100 ccm.	35 mg. per 100 ccm.
Cells	1 lymph. per c.c.m.	19 ep. th. as per c.c.m.
Clarity	Negative	Negative

The only appreciable difference between the fluids is that due to contamination in passage through the nose.

For over two months the patient was lost sight of and sought other advice. On reappearing he said that injections of corvix vaccines and various local applications and sprays were tried without success. He was then advised to take absolute rest in bed for six weeks. About the middle of the fourth week the flow gradually began to diminish and a week later it ceased. At the end of six weeks he got up. On two subsequent occasions—namely three weeks and three months following his recovery—he complained of moisture in the same nostril with a sensation that his trouble was returning but no actual dripping took place. An injection of a quarter of a grain of morphine cleared the moisture on both occasions. Morphine was not tried when the flow was profuse.

The patient is now following his usual occupation as a storeroom-keeper and is in perfect health.

## SUMMARY

1 Up to 1934 sixty six cases of cerebrospinal rhinorrhoea had been reported.

2 The condition may be associated with cerebral tumour or hydrocephalus which should be excluded.

3 Spontaneous cases are often spontaneously arrested. Some cases require muscle grafting—a relatively safe operation in expert hands.

4 Local applications are harmful.

My thanks are due to Mr Norman M. Dott of Edinburgh and Dr S. M. Katz of Johannesburg for their helpful advice.

## Reviews

## CIVILIZATION AND DISEASE

*Civilization and Disease* By C. P. Donnison M.D. M.R.C.P. With an Introduction by Sir Walter Langdon Brown M.D. F.R.C.P. (Pp. 222 10s 6d) London: Baillière Tindall and Cox 1937.

Dr C. P. Donnison's views on civilization and disease are based on medical work in a native reserve of Kenya Colony and in a good class practice in England and they therefore command more attention than writings on this subject which are mere arm chair speculations. From ratios worked out from statistics of colonial medical services and from his own experience in the South Kavirondo native reserve he concludes that hyperpiesia, Graves' disease, peptic ulcer, appendicitis, diabetes and psychoneurosis are diseases that show a close relationship with civilization. Constipation is not a phenomenon of civilization—it is of frequent occurrence in primitive natives—and malignant disease is by no means rare. The variation in disease incidence is not the result of hereditary differences for hyperpiesia is common in American negroes and psychoneurosis and schizophrenia are frequent in African natives in contact with civilization. Nor does it seem to be the result of differences in diet or hygiene. It can be most simply explained by differences in the emotional life. In primitive communities life is exteriorized and the individual is in almost all things submerged in the crowd. Emotions tend to be swiftly expressed and where instinctive urges and the needs of the community conflict a barrier or taboo exists to regulate conduct. For civilized man life is a much more individual adventure and the conditions of stress to which it gives rise can rarely be expressed in physical activity. Dr Donnison suggests that the pent up emotion acts through the hypothalamus either by way of the autonomic nervous system producing high blood pressure or peptic ulcer or by way of the anterior pituitary gland producing diabetes or hyperthyroidism. This is perhaps an oversimplification of the thesis which is discussed with reference to the doctrines of modern schools of psychology. The author concludes that the nature of the evolution of the human race is confronting mankind with a psychological adaptation which he does not achieve with ease and that the difficulties can probably be most simply explained in Adlerian terms.

## SURGERY IN BRIEF

*A Short Textbook of Surgery* By C. F. W. Illingworth M.D. F.R.C.S. (Pp. 702 179 figures 8 plates 21s) London: J. and A. Churchill 1938.

The title *A Short Textbook of Surgery* is bound to make an appeal to the hard working medical student or to-day and may be said to be representative of a modern tendency since within the last eight or ten years the word 'short' has appeared on the title page of a number of students' textbooks. Mr Illingworth's name is already known to a large number of students as the co-author with Mr B. M. Dick of a very successful textbook of surgical pathology and the present work should make it still better known.

Whenever an attempt is made to cover a large subject such as the science and art of surgery by a short textbook for undergraduate students the chief problem must always be what to include and what to omit in order to

give the student a balanced idea of the relative importance of various lesions. For this reason the author of such a work invariably lays himself open to the criticism that such and such has been omitted while emphasis has unduly stressed the importance of something else. The only safe criteria can be the relative frequency of occurrence and the degree of importance to the patient of a particular condition. Generally speaking the subject-matter has been well selected in this volume, but in its preparation the author might in places have been rather more definite—for example, in carbuncle of the lip (incorrectly referred to as hip on page 691 of the index) the reader is left in some doubt as to whether the angular vein should be ligated and the carbuncle incised. Many surgeons would regard both measures as distinctly dangerous and to be avoided. Complete thyroidectomy for various cardiac conditions might be thought to be given undue prominence in a short textbook for students, since opinion is not yet settled in regard to this procedure, which would appear to be falling into disrepute at such a rate as hardly to justify almost half a page of text in an admittedly limited work. Despite any such criticism, however, it is apparent that this little work has been carefully prepared to bring it well into line with current thought and practice, and as an example of this we may point to the description of the injection treatment of hernia. There are interesting chapters on post-operative complications, on radiotherapy and physiotherapy, and on surgery and diabetes.

The book is illustrated by line drawings, photographs, and x-ray plates. It is of convenient size and printed in clear, easily readable type. It will probably supplement some of the older works which have run to many editions—some recent editions have not been sweeping enough in their revision—and should prove popular with both teachers and students.

### ENCEPHALOGRAPHY

*The Normal Encephalogram.* By Leo M. Davidoff, M.D., and Cornelius G. Dyke, M.D. (Pp. 224, 149 figures 25s net.) London: Henry Kimpton, 1937.

This book correlates radiographic detail with normal anatomical structure, and accordingly includes description of the topographical anatomy of the brain together with radiographic detail demonstrable by air injection. The technique of encephalography is discussed, and a modified but simplified method recommended by the authors. Contra-indication to employment of the method appears in few cases, and its use is advised in all cases of organic neurological disease in which an actual diagnosis fails to be made. Modifications in technique are found in the limitation of the quantity of air injected, and the use of "trial exposures" after the injection of about 20 ccm of air, from the latter an estimate of the total amount of air necessary in a given case is made. Two series of views are recommended: one with the patient placed horizontally, and a further series in an erect posture. These series of stereoscopic views demand a large number of exposures (sixteen), but the authors state that there is little risk of epilation or erythema, even after a repeat series—according to the authors a minimum of forty exposures is essential to the production of irradiation effects on the skin. Stereoscopic views are essential to the recognition of the extensive detail that becomes decipherable.

The book is representative of a vast amount of work carried out by the authors in the production of an exhaustive description of data available to the careful

observer. The collection of 4,000 encephalographies indicates the material basis from which the knowledge is derived. Throughout the text is beautifully illustrated by well chosen radiographs. The authors' experiences may well prove of benefit to other observers in the interpretation of encephalographic findings, and the book is recommended for perusal by all interested in this form of investigation.

### ORGANIC CHEMISTRY

*Precis de Chimique Organique.* By Victor Grignard. Edited by Roger Grignard and Jean Colonge. Preface by Professor G. Urbain. (Pp. 774, 150 fr., bound, 175 fr.) Paris: Masson et Cie, 1937.

This volume is compiled on much the same plan as English textbooks of organic chemistry. It differs, however, from most English textbooks in that these are often limited in their scope to the work required for a particular examination, whereas Grignard's contains a more generalized survey of the subject and is less limited by the scope of the usual curriculum. Accordingly it gives more ample details of the properties of substances and indicates their relations to technical use when that is important. It does not, however, enter into the field of technology proper, and does not enlarge on the description of organic substances of natural origin except to indicate their chemical constitution where this is well known. The treatment of theoretical matters is exceedingly good. We do not remember seeing a better statement of the reasoning which leads to the accepted formula for benzene. A discussion of alternative formulae which harmonize with many of the properties of benzene, but which fail to explain certain other properties, is much more illuminative than the more usual brief account which describes the accepted formula only, with a recital of the points of agreement between hypothesis and experience. The nomenclature of substances corresponds with that in general use elsewhere than in France, and a clear explanation is given of the plan and scheme of nomenclature which finds modern acceptance. In the discussion of organic reactions a reference is regularly made to the name of the person associated with the discovery of the reaction or with its more extended developments. This is advantageous to students of organic chemistry, for they have not infrequently to encounter in literature a reference to a type of reaction under the guise of a personal name without any indication of its nature. For English readers the text presents no unusual difficulty, it is easy to read and the book is highly informative.

### THE BUSINESS SIDE OF PRACTICE

*The Physician's Business: Practical and Economic Aspects of Medicine.* By George D. Wolf, M.D. Foreword by Harold Rypins, M.D., F.A.C.P. (Pp. 384, 57 illustrations. No price given.) Philadelphia, London, New York, Montreal: J. B. Lippincott Company, 1938.

In the preface written by Dr. Harold Rypins for Dr. G. D. Wolf's book, *The Physician's Business*, there is a paragraph which is well worth the attention of every young man or woman on the threshold of a medical career. "The somewhat snobbish blindness of the professions," he says, "to the business aspects of their own occupation is regrettable. Whether he likes it or not, every professional man is engaged in a business of selling his professional skill and satisfying, if not increasing the number of, his customers. This implies, among other things, conservation of his and their time by means of method—and a thousand other 'vulgaries' not included in the strictly professional training or outlook."

Dr Wolf's aim is to fill in these gaps in the knowledge of the young practitioner in the United States of America and he has produced a guide to the business side of medical practice in that country which differs in some degree in its scope and method of approach from that recently published by Dr Theodore Wiprud reviewed in these columns on December 4 1937. A very large part of Dr Wolf's book as indeed of its predecessor deals with conditions which have no counterpart in these islands and is therefore not of strict relevance to our problems but so far as general principles go his advice is full of worldly wisdom. His thoroughness is perhaps best exemplified by the series of nine model letters he has composed which he recommends the doctor to post at intervals of fifteen days to any patient whose account has not been settled within three months of the services in respect of which it has been rendered. These model letters show a very nice gradation of polite firmness in the early ones he politeness is more stressed than the firmness and as the series goes on the proportions are gradually altered until the firmness outweighs the politeness. Alternatively he prints with approval a series of five forms prepared for doctors by an American firm in Ohio which are headed respectively Statement Reminder of Account Delinquent Statement Legal Demand for Payment and Five Day Notice.

### THE PATHOLOGIST IN INDIA

*The Medico-Legal Post Mortem in India* By D. P. LAMBERT M.D. Ch.B. D.T.M. and H. With a Foreword by Sidney Smith M.D. F.R.C.P.E. (Pp. 113 5s.) London J. and A. Churchill 1937.

Arduous and unpleasant as is the pathologist's task in this country in India it is even more so for putrefaction takes place so quickly that the corpse nearly always presents a most repulsive aspect. Identity may be established by features quite strange to the English mind—caste marks the style of cutting and dressing the hair and perforations and ornaments. Major Lambert has written a valuable and handy pocket guide for the pathologist in India describing in very economical language the technique of post mortem dissection the appearances of injury by various weapons and mishaps including the attacks of wild animals the various guides to identity and the signs of poisoning. He deals specially with infanticide and the technique of necropsy on an infant. He has covered a great deal of ground in a small space using language of the simplest and clearest. As Professor Sidney Smith says in a foreword there is no distracting discussion in the book and the practitioner will find in it a wealth of practical information. Most of the information will doubtless apply to work in other countries with similar climatic conditions.

### THE TROUBLED MIND

*The Troubled Mind. A General Account of the Human Mind and its Disorders and their Remedies* By Harry Roberts. With Chapters on the Insanities by Margaret Wilson Jackson. (Pp. 284 6s. net.) London John Murray 1938.

There is room for further popular books on psychology and this is very definitely a good one. Our only doubt is whether some literary dictator should not declare a close season for such volumes for the next five years at least. Those of us who are already acquainted with the work of Dr Roberts expect a high standard of shrewd common sense and of literary expression and a facility for dealing with the material and we are not disappointed. The recent flood

of psychological literature is usually lapped up by neurotic people who take it far too seriously and it is refreshing to find such statements as the following. There seems no justification for regarding the child as a blank book in which parents inscribe their mistakes in indelible ink.

The first few chapters are devoted to the general principles of psychology and psychopathology which are of course familiar enough. He does not think much of the full blooded Freudian doctrines though he admits as every honest student must Freud's enormous service to psychiatry is galvanizing the dead bones of academic psychology. There is a provocative chapter entitled

What is Sanity? and an excellent treatise on the neurotic from the point of view of the general practitioner who meets with so many of these difficult people in his daily work. The chapter on psychoses has apparently been largely contributed by Dr Jackson and is an admirable brief survey of the subject though it lacks the tang of Dr Roberts's own personal experience which characterizes the rest of the book. Similarly mental defect is surveyed and there are brief summaries of the methods of treatment of mental illness and a description of the legal requirements imposed by the State for the care and protection of patients and others. Altogether a wholly admirable book attractive to read and full of good sense and useful information.

### Notes on Books

*The Proceedings of the Sixth Conference of the International Association of Preventive Paediatrics* now issued contains a full account of the meeting held last year in Rome. The two subjects chosen for discussion were concerned with the organization of preventive inoculation against typhoid and secondly the part played by home visiting in the campaign against infantile morbidity. The volume is published at the price of three Swiss francs by the Union Internationale de Secours aux Enfants 15, Rue Levrier Geneva.

Dr R. R. KUCZYNSKI has brought together in a small volume *Colonial Population* (Miltord 5s.) not only all the recorded data of population in colonies or mandated territories but information on the way the data have been compiled. The book the compilation of which must have involved much labour will be useful for reference. Many of the citations from colonial reports suggest that as Major P. G. Edge pointed out recently in a paper read before the Royal Statistical Society vital statisticians still receive little official encouragement in colonial services.

*Der Schiffsarzt in a Hafenarzt* is published at Jena by Gustav Fischer (price RM. 6.20 or RM. 8 bound). Its purpose is to help the ship surgeon and port medical officer of health and also the ship's officer. It is the joint work of four medical men. Dr HEINZ SPRANGER medical officer of health and former member of the German National Health Council discusses the international hygienic armour of the German ship and harbour doctor and deals with the international field of hygiene. Dr EDUARD WOLF harbour and quarantine officer of health at Bremerhaven is the author of two chapters on the health supervision of ships in German harbours and on the task of the port M.O.H. especially in his relations to ships doctors. The editor Dr FRIEDRICH KORTENHAUS of Bremen contributes chapters on legal regulations for the care of the sick on preventive medicine in merchant vessels and on the M.O.H. and emigrants. The chapter on fighting infectious diseases on board ship and in harbour is by Dr FRIEDRICH HODER director of the State Hygienic Institute Bremen.

SATURDAY JUNE 4 1938

COLLAPSE THERAPY OF PULMONARY  
TUBERCULOSIS

At a meeting of a medical society last year the view was expressed by one with some experience in tuberculosis that it was not yet possible to form a just appreciation of the place of collapse therapy in the treatment of pulmonary tuberculosis. The cautious and conservative attitude behind this view is widely shared by workers in tuberculosis. *Festina lente* is a useful guiding principle for the therapist, and he who blows hot in advocating a certain measure usually soon finds himself blowing cold. But conservatism must stop short of being reactionary, and that a timid approach to the treatment of pulmonary tuberculosis by collapse measures is no longer justified is amply borne out by the recently published work of John Alexander<sup>1</sup>. The wealth of detailed information in this readable and fully illustrated book makes it a valuable publication on the subject. The author is able to show that ample experience is available for the clear ascertainment of the position of collapse therapy in treating the tuberculous patient. He maintains that from 50 to 80 per cent of all patients with the adult type of pulmonary tuberculosis admitted to sanatoria (and in the United States these include patients in all stages of the disease) are suitable for this form of treatment. Moreover, it is shown that it is of much value when employed at an early stage of the disease, and that it may therefore not be justifiable to submit patients to ordinary sanatorium routine for a prolonged period. The best results of collapse therapy are, Alexander asserts, obtained in early restricted lesions. He gives trustworthy and comparable figures which indicate that the results of sanatorium treatment with extensive use of collapse therapy are much better than those obtained by sanatorium treatment supplemented by little or no collapse therapy, patients with advanced disease being included in this comparison.

Among the factors that account for these different views is perhaps the tendency to concentrate on the relative merits of individual measures

rather than upon collapse therapy as a whole. Alexander stresses the importance of the latter. When the physician is faced with a patient suffering from pulmonary tuberculosis the question to be decided is not whether he needs an artificial pneumothorax, an apicolysis, or a thoracoplasty, but whether or not collapse therapy is indicated. The least serious method applicable to the particular case will then be chosen, to be followed by others the choice of which will depend on the effect obtained by the first. No fewer than ten distinct methods are described in the book. Further support for the conservative attitude is the belief that collapse therapy is applicable only to cases of unilateral disease. This view does not recognize that such measures as artificial pneumothorax and crushing of the phrenic nerve are revocable methods with almost no risk in relatively early lesions, that when properly carried out they do not affect adversely the other lung, and that ill effects are often avoided by insisting upon strict general rest at the same time. It is indeed imperative that the fundamental principle of rest in the treatment of pulmonary tuberculosis must not be overlooked in any advocacy of collapse therapy. The need for the closest co-operation between physician and surgeon throughout treatment is repeatedly emphasized by Alexander, who points out, however, that the prolonged training required by the thoracic surgeon has led to the present supply still falling short of the demand.

At the Michigan State Sanatorium the disease was arrested or rendered quiescent in 84.4 per cent of ninety discharged minimal cases (corresponding to our TB - and TB +1 groups), in 43.3 per cent of which collapse therapy (phrenic paralysis, pneumothorax, or both) was used, and in no less than 94.3 per cent of the thirty-five patients with minimal disease who remained under sanatorium treatment for six months or longer, all of whom had collapse therapy. On the other hand, at the Trudeau Sanatorium, during a period when little collapse therapy was employed, 26.5 per cent of 898 patients admitted with minimal disease were discharged as still "active," and three patients died in the sanatorium. In regard to remote results Alexander points out that the intensive expert use of collapse therapy in a majority of sanatorium patients is too recent to serve as a basis for a report of the results obtained in the whole population of any institution five or ten years after operation, but his twenty-five years' experience with collapse therapy strongly favours the assumption that a patient who is discharged with arrested or apparently arrested disease by collapse therapy has at least as good a chance of remaining well as a patient similarly classified who was not so treated.

## THE TRADE IN SECRET REMEDIES

The author and publishers have done a notable service in issuing a sixpenny monograph on *Patent Medicines for the ordinary reader*.\* Those who know anything of the matter realize as Professor A. J. Clark does the reluctance of the Press to deal with it. For the first time it we except the *Secret Remedies* and *More Secret Remedies* of the British Medical Association—now long out of print and in any case coming from a source suspect in many eyes—the public has the opportunity of learning the facts about this trade. It can also learn why Parliament and the Press have been inactive in dealing with a subject which might be thought to offer both of them a fine opportunity for that service to the public which they presumably exist to give. As Professor Clark says, "Politicians who depend on popular votes simply dare not offend the Press and still less dare the Press offend the advertiser upon whom it is entirely dependent for its existence." For this statement facts and figures are given which deserve careful attention. The trenchant report of the 1914 Select Committee of the House of Commons on *Patent and Proprietary Medicines*† is effectively quoted and Professor Clark has some mordant remarks on the extraordinary 'luck' that has favoured the Press and the trade in avoiding Parliamentary action. He does full justice to the ingenuity of the manufacturers and advertisers of secret remedies and to their astuteness in changing their methods with changing times and fashions. He notes and condemns the present fashion which often takes the form of an appeal to fear as well as to ignorance. He realizes however that there is a legitimate field for some of these remedies and that the best of our newspapers now exclude the worst forms of advertisement. In spite of progress in this direction (in which the British Medical Association and its *Journal* have been active if unobtrusive factors) he was able to find in one recent Sunday paper a cure for epilepsy, a drug that had cured mitral disease of the heart, varicose veins, piles, eczema, rheumatism and neuritis and finally a drug recommended for hay fever, asthma, malaria, influenza and insomnia in addition to the relief of most forms of pain. Evidently the appeal to the invincible credulity of the public pays.

Professor Clark welcomes the growing practice of publishing a formula but it is doubtful whether this change which avoids payment of stamp duty protects anybody. To the average man a chemical

formula means nothing. There is however one change in the situation not mentioned by Professor Clark which seems likely to do something to eliminate the more glaring abuses of patent medicine advertising. The association which includes the proprietors of many of the most advertised remedies has adopted the criteria included in the mild Medical and Surgical Appliances (Advertisement) Bill of 1936 which was 'talked out' in the House of Commons. The advertisements of all members of the association must conform to these criteria. This is welcome if belated evidence of the desire of the trade to reform itself. Professor Clark is rightly severe on the law which as he states and proves shows a remarkable leniency towards the vendors of quack medicines in strong contrast with the severe penalties to which those who misrepresent the character of ordinary foods and drugs are liable. In his opinion the medical profession cannot be held blameless in this matter. He points out among other things that reputable drug firms by adopting some of the methods of the baser members of the patent medicine trade have proved that doctors can be induced to use and prescribe expensive proprietaries though exactly the same drugs can be bought for less than a quarter of the price.

The Select Committee of 1914 found what the medical profession knew only too well—that there was a large and increasing sale in this country of patent and proprietary remedies and appliances and of medicated wines. It grouped these widely differing remedies into (a) genuine scientific preparations (b) unobjectionable remedies for simple ailments and (c) many secret remedies making grossly exaggerated claims of efficacy causing injury by leading sick persons to delay in securing medical treatment containing in disguise large proportions of alcohol sold for improper purposes professing to cure diseases incurable by medication or essentially and deliberately fraudulent. The third class of nostrums said the Committee constituted a grave and widespread public evil calling for new legislation rather than amendment of the existing law. In August 1920 when the Ministry of Health was a new thing and Lord Addison was Minister a Proprietary Medicines Bill was introduced into the House of Lords to regulate the manufacture and sale of certain medicines and surgical appliances and for purposes connected therewith. The object of this Bill introduced by Lord Astor then Parliamentary Secretary to the Ministry of Health was to give effect to the recommendations of the Select Committee but it struck at powerful vested interests and came to nothing. Professor Clark's little book may be strongly

*Patent Medicines* By A. J. Clark, M.D., F.R.S. Fact 19

recommended. We shall be interested to see whether it has any better luck in the lay press than other attempts to open the eyes of the public have had. It deals with a matter which gravely affects the health of the public—not to mention the public's belief in its own intelligence.

### "THE BEECHAM LABORATORIES"

The Royal Northern Hospital in Holloway Road, London, is a large voluntary hospital which does admirable work in serving an area of seventy square miles and a population of 1,000,000 in North London, and it has lately appealed for £350,000 to enlarge and modernize the buildings. It must have been with a feeling of dismay that the medical staff of the Royal Northern Hospital read last week a full-page advertisement in leading London newspapers. This was headed in bold lettering "The Beecham Laboratories recently presented to the Royal Northern Hospital, Holloway, London," and continued "Shareholders of Beechams Pills, Ltd., of St. Helens, will join their chairman and directors in wishing success to the new research laboratories presented to the hospital by their company. The laboratories are now an active department of one of London's great hospitals. Here the multitudinous drugs, sera, and vaccines used in daily practice are studied so that they may work safely and effectively." By a coincidence there appeared almost on the same day reports of the tenth ordinary general meeting of Beechams Pills, Limited. The chairman in the course of his speech said "The company owns and markets the following proprietary articles: Beechams Pills, Beechams Powders, Beechams Lung Syrup, Cassell's Tablets, Veno's Lightning Cough Cure, Cicfa, Dinneford's Magnesia and Tablets, Germolene Ointment and Soap, Holloway's Pills and Ointment, Iron Jelloids, Lactopeptine, Nicocin, Phensic, Phosferine, Ashton and Parsons Baby Powders, Phyllosan, Sherley's Dog and Cat Foods and Medicines, Yeast-Vite Tablets, Amami Shampoos, and other products." The action of the Royal Northern Hospital establishes a precedent which other voluntary hospitals, in their need, might be tempted to follow. There is no point in disguising the fact that the interests which Beechams Pills, Ltd., largely represent are ones which have been consistently opposed by the medical profession. It is obvious that the profession cannot have it both ways: it cannot decry the evils of patent medicines and self-medication and at the same time accept gifts from those who make profits out of such activities.

### INSULIN TREATMENT OF SCHIZOPHRENIA

The histological changes which may be produced in the brain by insulin therapy were first described in 1928 by Wohlwill<sup>1</sup>. In two diabetic patients who died in insulin coma he observed a variety of changes in the ganglion cells, glia, and axis cylinders, which he was unable to interpret. In 1933 Boddechtel<sup>2</sup> described severe changes in the nerve cells of the cortex and the striatum occurring also in a diabetic under treatment with insulin; he interpreted these as anoxic in origin. Since then similar cases have been recorded and systematic experiments have been made on dogs and rabbits. Weil and his co-workers in a careful study have summarized the literature and have provided experimental data of their own. The results obtained by experiments on animals are in substantial agreement with those obtained accidentally in man. The changes vary in distribution and to some extent in nature. The most constant findings are changes in the nerve cell—vacuolization and homogenization in the acute cases; shrinkage and degeneration in the more chronic—glial proliferation, and changes in the vessels varying from endothelial proliferation to small haemorrhages and softening. All these are to a large extent unselective in localization but occur with relatively greater frequency in the large masses of grey matter like the corpus striatum and the substantia nigra. It seems to be generally agreed that these changes are exactly similar to those produced by oxygen deficiency, and the suggestion is that they may be in part due to 'intracellular anoxaemia'. It seems possible that the presence of large concentrations of insulin incapacitate the cell for the utilization of available oxygen. These findings are of significance in connexion with the insulin treatment of schizophrenia. Weil considers that it is the total amount of insulin given that is important. Very large doses in a single day do not produce recognizable changes. More moderate doses on a number of occasions, adding up to a greater amount, may give rise to irreparable changes. The number of seizures is not important. Severe damage was produced in the brains of rabbits by doses of 200 units of insulin. Corresponding doses, in units per kilogramme, are not infrequently given in the insulin treatment of schizophrenia. One cannot argue directly from rabbit to man, and it is possible that the rabbit is more susceptible to permanent damage from insulin, as to the toxic effects of many drugs, than man is. Deaths in or after insulin coma are uncommon but have been met with in the insulin treatment of schizophrenics. So far there has been no satisfactory record of the pathological findings. We are almost as completely in the dark about the pathological as about the therapeutic *modus operandi* of insulin therapy, for, apart from the histological aspect, complex biochemical problems require elucidation. The results of animal experimentation suggest the possibility of neurological damage being found as a late sequel of the insulin treatment of schizophrenia. This danger cannot be dismissed, but an estimation of its importance will rest on clinical experience.

## CONTACT LENSES

When Jean Méry in 1703 found that the luminosity of the cat's eye could easily be viewed when the animal was held under water he dimly foreshadowed the coming of the ophthalmoscope and the contact lens for the optical principle involved was as de la Hire showed six years later the abolition of the corneal refraction under water. These observations ultimately led to the ophthalmoscope in 1851 but it was not until 1888 that a clear recognition of the value of abolishing corneal refraction was propounded by Fick. Theoretically the abolition of the cornea as a refracting medium by surrounding its outer surface with fluid of a similar refracting capacity as the aqueous of its inner surface could be used to eliminate not only corneal astigmatism but also such distortion in vision as an irregular cornea would give; moreover extensive modifications in the total refraction of the eye could be brought about by moulding the glass which supports the outer layer of fluid to any desired optical strength. Technical difficulties prevented this theoretical conception from being realized in practice. The production of glass hard enough to withstand the corroding action of tears malleable enough to be moulded to fit the globe and sufficiently rigid to stand grinding to give both accurate fitting and a desired optical strength presented difficulties that could not be overcome. Occasionally a lens satisfying these criteria was produced by glassblowers such as by Müller of Wiesbaden but the lack of uniformity in results made such success a matter of chance. To these technical difficulties was added the fact that after all a contact lens was as its name implies a foreign body in actual contact with the eye and the eye does not readily tolerate even the most innocuous of foreign bodies. The pioneer efforts of Fick were therefore not followed up until about ten years ago when the firm of Zeiss brought out contact lenses which were satisfactory so far as the technical requirements of glass manufacture were concerned. They could produce contact lenses according to prescription and had gone far in making these lenses tolerated as foreign bodies by introducing a large range of scleral rims to fit the eye accurately. None the less theirs was essentially a technical achievement for in actual use it soon became apparent that the spherical rims of the Zeiss contact lens did not satisfy the unsuspected astigmatism of the sclera. The lens therefore did not fit accurately on to the sclera and occasionally touched the cornea especially with slight movements of the lens which resulted from inaccurate apposition to the sclera. A third stage in the evolution of the contact lens was reached with the work of Dallos, formerly of Budapest and now of London. To Dallos the problem amounted to individual fitting of the contact lens though of course he could not have launched on his work until the technical difficulties of the manufacture of the glass had been solved. Essentially his approach had been that of taking a cast of the anterior segment of the eye and grinding the glass according to the cast with final adjustment on the patient. Even so the final adjustment of the

lens rim to the sclera may be the most tedious part of the process. Broadly speaking it may now be held that the technical difficulties of the manufacturer and the individual difficulties of the surgeon and the patient are within sight of being overcome. A number of centres are being established by different authorities where these problems are now being worked out on a far larger scale than hitherto. The use of the contact lens has many advantages. The optical problems have so far received rather less attention than the mechanical difficulties but it is clear that with a powerful and pliable means to modify the total refraction of the eye it will be possible to obtain results such as ordinary correcting lenses cannot achieve. An increase in the field of vision in high myopia, a closer correspondence between unequal retinal images in anisometropia—natural or after cataract extraction—an increase in visual acuity in high astigmatism and myopia—these are some of the physiological possibilities. They are not negligible but of even greater moment are the advantages that are gained by eliminating corneal erosion on such as is seen in conical cornea. Other uses have emerged. Different forms of keratitis are said to be beneficially affected by the wearing of a contact lens and even cosmetic advantages are possible by the use of a suitably tinted contact lens to hide a grossly damaged cornea from view. None the less it must not be assumed that contact lenses are a panacea. The cost is still prohibitive and the sum total of experience gained with lenses that can be tolerated in wear is as yet relatively small.

## RANCIDITY IN EDIBLE FATS

Problems of nutrition are much to the forefront at the present moment and it has been rightly considered an opportune time by the Department of Scientific and Industrial Research to issue a special report dealing with one of the most important food constituents—namely the fats. While the main theme of rancidity is a seemingly unattractive one to those not specially engaged on food investigation the volume is comprehensive enough to cover a number of matters of interest to the general medical reader. For example it begins with an excellent section dealing with the biochemistry of the fats which as a practical exposition will be found of more absorbing interest than the same subject as treated in the ordinary physiological textbook. Moreover this impressive introduction in itself will act as a strong inducement to the reader to proceed further and examine the report in so far as it bears upon certain other points of more general interest of which three might be instanced. These are the limitations of the senses of smell and taste as ultimate standards in the recognition of deterioration the correlation between these and standards based upon chemical tests and the possible fate of the fat soluble vitamins in relation to the phenomenon under discussion.

## CHEMOTHERAPY AND CANCER

For several years L. C. Strong of Yale has studied the effect of oil of wintergreen given by mouth in small doses to mice with spontaneous mammary cancers. The tumours completely regressed in a few mice and in others there was a significant prolongation of life.<sup>1</sup> Redistilled synthetic methyl salicylate was without effect.<sup>2</sup> Fractional distillation of the true oil yielded a "high" fraction which like the synthetic product, was inactive and a "low" fraction somewhat more active than the original oil. Both fractions contained methyl salicylate. Administration of the low fraction increased the average period of survival after detection of a tumour to seventy-five days compared with fifty-five days in the controls. Complete regression occurred in four out of thirty-four mice and only when treatment was started while the tumours were small.<sup>3</sup> It now appears that the active component of oil of wintergreen is heptyl aldehyde. This compound caused liquefaction and complete regression of tumours in six out of twenty-five mice though neither liquefaction nor regression was observed in 120 control mice.<sup>4</sup> These figures if not spectacular, are probably reliable, which is more than can be said for most therapeutic experiments on cancer. One technical difficulty is to obtain spontaneous tumours in large enough numbers to yield results which withstand statistical analysis, knowledgeable experimenters deliberately avoid transplantable tumours. Strong uses an inbred strain of mice in which mammary cancer develops with a high and regular frequency, and so obtains a relatively homogeneous material and abundant controls. The price paid for these advantages is that the tumours are dubiously representative of cancer in general. Granted that heptyl aldehyde has an important action on a particular kind of tumour growing in a particular kind of mouse, it is not a foregone conclusion that the compound will act similarly on other tumours and in other animals. So far as can be judged at present the action is exerted upon the stroma and vascular system of the tumours rather than upon the parenchyma cells, and, if this be true, cure probably depends on peculiarities of stroma and blood vessels which render some tumours exceptionally vulnerable. In Strong's view there is an enhancement of the defensive processes which sometimes cause spontaneous regression of tumours. Hitherto, defensive reactions against spontaneous tumours have not yielded to experimental analysis, though there is a considerable weight of clinical evidence that they operate in human beings. If Strong's experiments demonstrate that a defensive mechanism can be stimulated by chemotherapy, they have a fundamental importance which is not dependent on the practical value of heptyl aldehyde as a therapeutic agent. This substance will no doubt receive prompt attention from laboratory workers, there is no question of its immediate use for human cancer. Strong makes no extravagant claims, and is content to suggest that spontaneous tumours, in mice at least, may eventually be cured by chemotherapy.

## ROAD ACCIDENTS AND ILL-HEALTH

The medical profession in France has always stressed ill-health as an important cause of accidents on the road, and according to Professor Pierre Parisot and Dr G. Richard<sup>1</sup> the French roads carry about 2,155,000 four wheeled vehicles and half a million motor cycles, which cause 3,000 to 4,000 deaths and 50,000 to 70,000 injuries a year. The human factor is responsible, according to various authors for between 40 and 75 per cent of these accidents. They press for medical examination for all drivers and complain that the legislature will not pay proper attention to the matter, although fourteen European countries have adopted this safeguard for all drivers and three others for public service vehicles. France already has it for drivers of public service vehicles and of heavy transport. They point out that since a large concern managing omnibus services introduced the medical examination more than ten years ago its accidents have dropped to less than half. In 1929 it relaxed the rule on account of the straitened means of most of its applicants and the figures for that year rose appreciably. This, however, is the only statistical evidence they adduce to show that a serious number of accidents are caused by a fault in the driver's physical or mental condition. They quote a few individual cases of serious accident caused by elderly drivers succumbing at the wheel to the effects of high blood pressure. In this country the legislature has tended to take a middle course, which represents, so far as can be judged, a working compromise and of which these authors, although they have studied our traffic problems, do not seem to have heard. When the whole question was under review by Parliament in 1930, the provision adopted to ensure a reasonable standard of health in drivers was that every original applicant for a driving licence should sign a declaration that he did not suffer from epilepsy or from sudden attacks of disabling giddiness or fainting and that he was able to read the registration plate of a motor car at 25 yards; also that he should disclose the loss of a hand or foot, or any defect in movement, control, or muscular power of a limb. He must also declare that he is not suffering from any other mental or physical disease or disability that would be likely to make him a dangerous driver. For epilepsy, certified mental disorder or defect, giddiness or fainting and lack of power to read a number plate, the licensing authority is bound to refuse the licence, but for any other condition the applicant may claim a test, and if he passes it he may have his licence. The licensing authority may revoke a licence if it appears to them that the holder is suffering from a dangerous disability, and here again he may claim a test unless the disability is one of those which absolutely bar the issue of a licence. He has an appeal to magistrates from a refusal. A licence holder who asks for a renewal must declare that his condition has not deteriorated. The would-be driver of a public service vehicle must produce a medical certificate of fitness and afterwards renew it every three years. The question of road accidents and their prevention is raised frequently in both Houses of Parliament, but this is

<sup>1</sup> *Bull Acad Méd Paris*, 1938, 119, 122

not one of the points that speakers consider to be important. There are no statistics and there is practically no informal evidence to show that failure of health in a form which could be detected by medical examination causes an appreciable number of accidents. If Parliament really regarded the traffic problem as a vital one it would sternly remove from the roads every driver who did not satisfy a fairly high standard of skill and of physical and psychological fitness. We in this country consider however that on balance it is better to accept a large casualty list and to allow every citizen to drive who passes an elementary test of proficiency and does not suffer from an obviously dangerous disability. The British have always been willing to pay a high price for the liberty of the subject.

### EXAMINATIONS

Pamphlets issued some two years ago by the English International Institute Examinations Inquiry Committee entitled "An Examination of Examinations" and "The Marks of Examiners" and the controversy which arose out of them will still be in the minds of those who are interested in assessing the place and value of examinations in our educational system. There were two other publications bearing on the same subject issued under the same auspices and the committee has now issued a fifth. A Conspectus of Examinations in Great Britain and Northern Ireland, compiled by Sir Philip Hartog with the assistance of Miss Gladys Roberts, Sir Michael Sadler, the chairman of the committee and Sir Philip Hartog, the director of the inquiry, in a preface explain the general object of the book thus: "The committee regarded it as desirable to publish for the information of persons interested in education in this country and abroad, as well as for the general public, a sketch showing the width and variety of the field covered at the end of the first third of the twentieth century by the examination system in Great Britain and Northern Ireland. The publication certainly succeeds in doing this, but it is not clear who exactly are the persons among the public or among those interested in education for whom it is likely to be of particular value. The examinations established for various purposes, degrees or diplomas by the several universities, colleges and local education authorities and the examination requirements for entry upon different professions or careers are ascertainable without difficulty in the case of each, and the number of persons who require this knowledge with reference to more than one or two without at the same time needing official information as to courses of instruction as well as to mere examinations must be very small. Nevertheless, if there be any such body of persons they will be admirably served by this conspectus. It is full, well arranged and so far as can be ascertained accurate at least for the years 1933-6. Perhaps the most revealing and generally useful section is that dealing with the procedure adopted for examinations conducted under statutory authority for admission to specified professions and callings. This includes not

only those relating to solicitors, medical practitioners, veterinary surgeons, pharmacists, nurses, midwives and architects, but those for teachers, civil servants, mine managers and surveyors, masters, mates and engineers of merchant ships, shippers of fishing boats, pilots, air navigators and drivers of public service vehicles and taxicabs.

### NARCOTIC POISONING

Poisoning by barbiturates, either accidental or suicidal, has attracted much attention in recent years and Dr Roche Lynch in his presidential address to the Society of Public Analysts and Other Analytical Chemists has given an interesting review of his experience of this problem particularly with regard to its chemical aspects. His observations are based on the study of well over 100 cases of barbiturate poisoning, most of which appear to have occurred in the last ten years. It is of interest to note that this figure is considerably smaller than those recorded in similar French publications and barbiturate poisoning seems to be much rarer in this country than in France. The mortality in the series was 56 per cent, but it is satisfactory to learn that the percentage of recovery has risen during the last six or seven years owing to improved methods of treatment. The important advances mentioned were the frequent performance of lumbar puncture coupled with saline injections and the use in full doses of analeptics such as strychnine. Chemical analysis of urine showed clearly the difference as regards rate in the body of stable barbiturates such as veronal and of shorter acting compounds such as dial. Substantial amounts of the former compound were regularly recovered from the urine while only traces of dial were thus found. Dr Roche Lynch described a quick method for the detection of barbiturates in the urine which would permit an analyst to diagnose barbiturate poisoning in fifteen minutes. He also discussed thirty cases of morphine poisoning and mentioned that although it was not difficult to recover morphine from the viscera of a normal person after poisoning yet this might be very difficult in an addict. He stated indeed that if the taking of a large dose of morphine was established and the drug could not be found in the viscera this suggested the probability of morphine addiction. In connexion with morphine he made some valuable comments on the lethal doses which are copied from textbook to textbook for generations and are solemnly quoted in the courts. For instance it is regularly stated that the smallest fatal dose of tinct. opii recorded in an adult is 2 fluid drachms. This however occurred in 1840 when opium was not standardized as regards its morphine content and when pharmacists made their own tinctures with varying skill. Hence the amount of morphine contained in the 2 fluid drachms in question was completely uncertain. Dr Roche Lynch's comment was "This is an example of many unsound observations which abound in textbooks on this subject and it is to be hoped that one day a book will be written which has eliminated such misleading and unreliable statements."

# SURGICAL PROCEDURES IN GENERAL PRACTICE

*This is one of a series of articles contributed by invitation*

## FRACTURE OF THE NASAL BONES AND EPISTAXIS

BY

W. M. MOLLISON, M.Ch

Fracture of the nasal bones is always due to direct violence and is usually a simple one. The line of fracture is either at the junction of the nasal and frontal bone, or, much more often, near the free end of the nasal bone. There may be no displacement and no disfigurement beyond extensive bruising, and the fracture may only be discoverable by x-ray examination. The whole nose may be displaced towards one side or may be depressed. In this case replacement is undertaken under general anaesthesia. Walsham's forceps are useful here, though any blunt flat instrument will serve, this or one blade of the forceps is introduced into the nose to correct the deformity, alternatively, the blades of the forceps are placed in the nostrils and the nose forcibly straightened. This method has the advantage of straightening the septum, too, if it is involved. A frequent result of blows on the nose is effusion of blood between the septum, which may be fractured, and its perichondrium—the so-called haematoma of the septum. Treatment is dealt with under the heading of epistaxis. Fracture of the nasal bones may be compound, care must here be taken with skin wounds to avoid subsequent infection and possible necrosis.

Complicated fractures are becoming more common, as Professor Cairns has pointed out, on account of car and aeroplane accidents. Owing to the great violence connected with these accidents not only are the nasal bones fractured but the anterior fossa of the skull may be involved. If the dura mater is damaged cerebrospinal fluid may leak through the nose or into the subcutaneous tissues. In either event the position of the patient is one of great danger from infection.

### Epistaxis

The commonest form of epistaxis, or bleeding from the nose, is that known as 'spontaneous', it is especially frequent in children and young adults. In general it is of small account, but it is always a great inconvenience, since it occurs without warning and interferes with work or social activities. It often stops within a few minutes, but it may continue for an hour or more and in rare instances be so profuse as to endanger life.

The cause of spontaneous epistaxis is not known, it is due to the giving way of the wall of a small vessel on the anterior part of the septum nasi. It may be actually started by blowing the nose or by scratching, but often the bleeding comes on without any apparent reason. There is some evidence that it is more prone to occur at the time of the menstrual periods, indeed, the epistaxis has been considered as vicarious menstruation. The predisposing factors to epistaxis are high blood pressure, albuminuria, arteriosclerosis, mitral stenosis, and some anaemias.

### AETIOLOGY

The onset of acute infections—for example, measles, influenza, and particularly those due to haemolytic

streptococci—is frequently accompanied by epistaxis. There are many other causes, some local and others general, these are here grouped more or less in order of frequency.

1 *Traumatic*—Blows on the nose, foreign bodies in the nose, fracture of the nose—nasal cartilage or bones, post-operative—reactionary and secondary bleeding.

2 *Local Nasal and Nasopharyngeal Diseases*—Diphtheria of nose, pneumococcal rhinitis, lupus, New growths. Malignant Carcinoma, either of the nasal wall or of the paranasal sinuses ulcerating into the nose, circumscribed polyp, sarcoma of the nasal lining, melanotic sarcomatous polypus. Innocent Bleeding polypus of the septum, nasopharyngeal fibroma, both rare.

3 *Ossicles Disease*—This disease, while rare, is often familial. The lesions are small circumscribed tumours of the blood vessels, affecting the skin, mucous membrane, and internal organs. The little nodules consist of dilated capillaries without elastic tissues or muscle, often having only a single layer of endothelium. These nodules may occur in the nose, generally on the septum. If one of them is destroyed by cauterization fresh crops appear round the destroyed nodule and further bleeding occurs, removal of the whole of the septum and its mucous membrane has therefore been suggested. This stops the bleeding but leaves crusting of nose. The bleeding from these nodules is easily stopped by the diluting bag described below.

### Treatment

Treatment consists essentially in dealing with the cases of *spontaneous epistaxis*, since all the other cases demand special treatment and are beyond the scope of these notes.

Cases may be divided into two classes (a) emergency cases in which the haemorrhage is severe or profuse, (b) ordinary recurrent cases in which treatment is prophylactic, to prevent future attacks.

### "EMERGENCY EPISTAXIS"

The patient should keep the head erect so far as possible, to prevent blood running down the throat. The quickest and most efficient way to stop the bleeding is by the use of a Cowper Rose bag. This consists of a thin catheter with a rubber finger-stall attached in such a way that the eye of the catheter is inside it. Air blown into the catheter will inflate the finger-stall, and a tap on the end of the catheter will keep it inflated. Smearred with petroleum jelly, the deflated instrument is pushed into the nose, inflated, and left *in situ* for some hours if necessary. Pressure is thus exerted on all parts of the mucous membrane, stopping bleeding efficiently and painlessly. This is the most reliable method of dealing with emergency epistaxis. Patients and practitioners would be spared much anxiety if one of these bags were always available. An alternative method is to plug the nose with ribbon gauze, either plain or impregnated with adrenaline or with "stryphnon" powder, a good light is very helpful, and the gauze should be placed first along the floor and then built up on this to fill the nose. This procedure is apt to be painful and to damage the delicate nasal mucous membrane.

Very occasionally bleeding occurs from so far back that the blood runs down from the posterior nares. Should the inflated Rosen bag fail to control the bleeding a plug may be placed in the posterior nares; this procedure however should only be used as a last resource since it is so painful. A thin rubber catheter smeared with petroleum jelly is passed through the bleeding side of the nose till it can be seen in the pharynx; it is then drawn through the mouth and a strong silk thread fastened to it so that when the catheter is withdrawn from the nose this silk thread takes its place. A small piece of rubber sponge (or a small mass of gauze) is fastened to the mouth end of the silk and carefully guided under the soft palate as the silk is pulled out of the nose; the sponge thus being firmly but gently fixed in the posterior nares. This procedure can be combined with plugging of the nares. To avoid infection of the middle ear via the Eustachian tubes the post-nasal plug must not be left in for more than twelve hours. Hydrogen peroxide (2% to 5% solution) is sometimes very useful in stopping haemorrhage; a strip of narrow gauze soaked in the solution is packed into the nose and left for some time.

#### SPONTANEOUS RECURRENT EPISTAXIS

In the majority of cases bleeding arises from the anterior part of the septum the so-called Kiesselbach area. Between attacks the mucous membrane of the septum may appear almost normal; in order to discover the origin of the bleeding the mucous membrane should be gently rubbed with a wooden probe carrying some wool; this procedure often starts the bleeding. A small flat-tipped pledget of wool moistened with adrenaline chloride 1 in 1000 and cocaine 10 per cent in equal parts is then applied to the bleeding area and kept in position by pressing the ala nasi inwards for a few minutes. The bleeding spot can then be touched or scorched with a flat cautery point at dull red heat. Alternatively a drop of pure carbolic acid on wool may be used or a bead of solid silver nitrate fused on to a probe be applied.

In some cases the bleeding point is found on the floor of the nose; in others bleeding is from a vessel running upwards immediately next the mucocutaneous junction on the septum; in this case it is difficult to avoid pain through overheating the skin. To prevent this flat flakes of wool moistened with water may be arranged on the skin before cauterization. In many cases of epistaxis in persons over 50 and in those whose blood pressure is high, the bleeding though profuse and sometimes alarming is no bad thing and it is often noticed that the pulse of these patients is full and of moderate rate even after some hours of epistaxis. The same remark applies to those with albuminuria or with chronic nephritis.

#### Traumatic Epistaxis

Even slight blows on the nose may cause epistaxis. The bleeding ceases spontaneously as a rule but if it persists it must be treated on the same lines as spontaneous epistaxis described above.

As well as the immediate epistaxis a blow commonly in children the result of falls on to the face may produce an effusion of blood between the mucoperichondrium and the cartilage of the septum the so-called haematoma of the septum which causes bilateral swelling of the septum and therefore obstruction to nasal breathing.

#### TREATMENT

This consists in incising the swollen mucous membrane over the septum in adults under local cocaine anaesthesia in children under general anaesthesia—for example ethyl chloride. Since the haematoma invariably suppurates pus will be evacuated unless operation is performed shortly after the accident. If the haematoma is not evacuated there is a considerable risk of necrosis of the septal cartilage and subsequent saddle deformity of the nose.

#### Foreign Bodies

The epistaxis caused by the presence of a foreign body is mild and is accompanied by unilateral mucopurulent nasal discharge. Removal of the foreign body is the appropriate treatment. In infants this can quickly be done without an anaesthetic older children may need short anaesthesia. The child is laid flat on a couch supported on a blanket and the head is held rigid. A straight rod—a gag—serves well—is passed along the floor of the nose and when beyond the foreign body is levered upwards and slowly removed bringing the foreign body with it.

In severe accidents to the nose involving the nasal bones or frontal sinuses and ethmoidal and the anterior fossa of the skull bleeding may be accompanied or followed by discharge of cerebrospinal fluid. The only treatment for this condition consists in preventing infection from entering from the nose apart therefore from highly plugging the nostrils with wool active local treatment must be avoided.

Perhaps the most alarming epistaxis is that of acute haemolytic septococcal infection of the upper respiratory tract so severe and persistent is it that blood transfusion may be required and indeed is probably the best treatment. The bleeding is especially embarrassing if an anaesthetic is needed for an operation—for example on the mastoid—since it may recur or continue during administration of the anaesthetic.

### INTERNATIONAL SOCIETY OF SURGERY

Vienna, September, 1938

The German Surgical Society to which most of the Austrian members of the International Society of Surgery belong is at present actively engaged in full collaboration with the Viennese Committee in ensuring the success of the Society's congress which is due to take place in Vienna from September 19 to 22. The sessions will be held in the Konzerthaus where radio-telephonic service is to be installed so as to ensure that everyone in the audience may hear the various speakers in the language of choice.

Reports on the following subjects will be discussed: Surgical treatment of hypertension, bone grafts and surgical treatment of pulmonary cysts and tumours. Nearly two hundred speakers have already signified their intention to participate in the discussions.

On the occasion of this congress the Messageries Maritimes are organizing a cruise which will leave Marseilles on September 4 and will give surgeons the opportunity to participate in operative demonstrations at Naples, Athens, Istanbul, Odessa, Bucharest, and Budapest. The cruise is due to reach Budapest by September 18 and arrival in Vienna is scheduled for 7.25 p.m. on that day. The same evening the Viennese surgeons are organizing a visit to the "Kursalon Stadtpark." Travel arrangements for British visitors are in the hands of Messrs. Thomas Cook and Sons.

## Nova et Vetera

### THE DIARY OF AN EIGHTEENTH CENTURY SURGEON

John Knyveton was born at Bromley in Kent on September 16, 1729, and died at the age of 80 on November 25, 1809. His father, a doctor, died when he was young, and he served his apprenticeship with an uncle. Mr. Ernest Gray tells us that Knyveton kept a diary in the year 1751-2. A perusal of the book<sup>1</sup> shows that such a diary was written, but it is so overlaid with embroidery by the editor that it is impossible to discover how much is original. It would perhaps have been better to publish the text and the comments separately. As it stands it is disguised by an imitation of Samuel Pepys's *Diary* (which was practically unknown until 1822), and is full of mistakes owing to ignorance of the conditions of medical education in the middle of the eighteenth century. But if these blemishes are allowed to pass the book makes interesting reading. It is divided into two parts, the first dealing with the life of an apprentice 'walking the hospital', and the second his service in the Navy as mate of a sixth rate. During his year in London Knyveton went through what may be supposed to be the ordinary experiences of a youth from the country: attended hangings at Tyburn, took part in 'resurrections,' and was present at many social parties. He could not, however, have attended a lecture at St. George's Hospital, where William Hunter spoke with the voice of John, his younger brother, neither could he have himself amputated by the flap method, because it was not yet in use. The service at sea is more probable. He tells of the hardships which had to be endured: of the floggings, which were frequent, of the general callousness to pain and of the recoveries which took place in spite of foul quarters, of bad rations and of offensive water. The picture is not overdrawn and makes the hygienic work of Captain Cook—a few years later—stand out in even higher relief than usual. There are nine illustrations, which are well reproduced, though it may be noted that Scultetus's name is wrongly spelt on the legend of "An Early Blood Transfusion".

### TWO BIBLIOGRAPHIES

#### Ambroise Pare and Sir Kenelm Digby

*A Bibliography of the Works of Ambroise Pare.* By Janet Doe (Pp. 266, 29 figures, Frontispiece, 22s. 6d. net). Chicago: University of Chicago Press. London: Cambridge University Press, 1938.

*Sir Kenelm Digby: Writer, Bibliophile and Protagonist of William Harvey.* By John F. Fulton, M.D. (Pp. 75, 6 figures). New York: P. and K. Oliver, 160 East 83rd Street, 1937.

These two volumes show that bibliography may be approached from two very different angles. Miss Janet Doe, assistant librarian of the New York Academy of Medicine, writes of Ambroise Pare, stating where the different editions are to be found; Dr. Fulton issues a critical review of the life and works of Sir Kenelm Digby, and appends a short-title list of his writings. Both are excellent in their way and will be of great service to future commentators.

Miss Doe supplements, brings up to date, and corrects Malgaigne's classical edition of Pare's complete works, which was published in three volumes in 1840-1. She contributes a very readable preface, and has chosen the illustrations with care, though she might, had she been so

minded, have added in account of the various portraits, for the iconography of Pare is still in need of attention. Miss Doe gives in account of seventy-three editions of Pare's works ranging from the first pamphlet of 1543 to a Japanese abstract in 1769. She discusses two difficult points in connexion with her subject—the first as to the religion of Pare, arriving at the conclusion that he was probably a Protestant who conformed to Catholicism. Secondly, as to the English translator of the 1634 edition, Lieutenant Colonel Thomas Johnson, who died of wounds received during the siege of Basing house in Hampshire, she has not been able to fix the date of his birth, but has very little doubt that a considerable part of the translation came into his hands from George Biker, an Elizabethan surgeon of whom little is known except that he lived at a time when the London surgeons were doing much literary work of a high character.

Dr. Fulton makes Sir Kenelm Digby live again in his essay. The father was hinged for complicity in the Gunpowder Plot and throughout his life the son steered a chequered and successful career through the stormy waters of the Caroline, Cromwellian, and Restoration periods. He seems to have engaged in the Catholic plots of 1641: is a friend of Queen Henrietta Maria, once at least he was a pirate, and he was a great lover, for on his beautifully bound books he intertwined his own initials with those of Venetti, his wife, so long as she lived. He always exercised great literary influence and was friendly with Ben Jonson, Selden, Hyde, Evelyn, and Thomas Randolph. To many he is known only by his *Powder of Sympathy*, to others by his observations on Sir Thomas Browne's *Religio Medici*. Dr. Fulton points out that he was the champion of Dr. William Harvey, and thus followed in the footsteps of Descartes, whom he knew personally. The little book is well worth reading and has some excellent illustrations. It is the outcome of a paper read at the Grolier Club, and is issued from the Laboratory of Physiology at the Yale University School of Medicine.

D'A P

### SPLENECTOMY IN 1887

Fifty years ago, on April 10, 1887, Sir Thomas Spencer Wells reported before the Royal Medical and Chirurgical Society of London (*Medico-Chirurgical Transactions*, 1888, 71, 255-63) a successful splenectomy which he had performed on December 5, 1887. The patient was a girl of 24, whom he had treated for some time with ergot, believing her abdominal tumour to be a large fibroid. The discovery at operation of an enlarged spleen came as a complete surprise. The pathological specimen was examined by Sir Frederick Eve at the Royal College of Surgeons and was reported to weigh 1 lb. 14 oz., after draining out a quantity of blood variously estimated as 3 to 5 lb. The surgeon cured the patient without knowing why, for her disease—acholuric haemolytic jaundice—was only described in 1900 by Oskar Minkowski. In opening the discussion on splenectomy at the Centenary Meeting of the British Medical Association six years ago Lord Dawson related that this patient was still living and that her only son had been one of his early cases (*British Medical Journal*, 1932, 2, 699). Spencer Wells's first operation for ruptured spleen—the first in Great Britain in modern times—took place in 1865.

Matthias de Lobel, or Lobel (Lobelius), after whom the genus *Lobelia* was named in 1702, was born 400 years ago at Lille, which then belonged to Flanders. Doctor of medicine of Montpellier University, he was for a time physician to William the Silent, Prince of Orange. A distinguished botanist, he spent the greater part of his life in England, where he wrote several works on plants in Latin, and died in 1616. His system of classification based on leaf form, was superior to those of earlier botanists.

<sup>1</sup> *The Diary of a Surgeon in the Year 1751-1752.* By John Knyveton. Edited and transcribed by Ernest Gray. (Pp. 322, 9 illustrations including a frontispiece, 10s. 6d. net). New York and London: D. Appleton Century Company, Inc., 1938.

## VOLUNTARY HOSPITALS EMERGENCY BED SERVICE

On May 27 in his presidential address to the Council of King Edwards Hospital Fund for London R.R.H. the Duke of Kent announced a project for centralizing the admission of emergency and acute cases to London voluntary hospitals. The Council considering this project to be one of great importance to the hospitals as being likely to improve the service rendered to patients and doctors alike passed a resolution to provide staff and funds to establish and operate it.

This is the final step in a long process which was begun in 1936 with the suggestion made to the Voluntary Hospitals Committee, County of London by a member of the surgical staff of University College Hospital. Since then the whole problem has been carefully studied by this committee and finally a skeleton scheme was placed before the hospitals for their approval which was given unanimously. The committee was then faced with the necessity of finding financial support and before making any general appeal approached King Edwards Hospital Fund. The Fund has agreed to provide support up to £3000 per annum and it now remains only to organize the office and open it as soon as possible. The responsibility for this task lies with a joint committee of the Voluntary Hospitals Committee and the King's Fund under the chairmanship of Sir Harold Wernher. The preliminary organization is now far advanced and it is intended to open the service on June 21.

### The Purpose of the Service

The service is intended to benefit all concerned in the admission of an emergency case. First of all the patient will be saved an unnecessary period of waiting which will in itself help towards his ultimate recovery. Secondly the doctor will be saved much time since he need only make one telephone call to find out the state of beds in any hospitals he may think suitable. Thirdly the hospital will never it has no beds to offer will be saved the trouble of answering the telephone uselessly. Thus a weakness for which the voluntary system is often criticized will be repaired.

To ensure successful co-operation it has been necessary for some hospitals to do a great deal of internal reorganization in connexion with the admission of patients in order that no delays may be encountered by the service. The hospitals by supporting the service are also giving special help to doctors in that they are largely abrogating their own selective powers so far as emergency cases are concerned. The hospitals will naturally reserve the right to refuse to retain in their wards cases which are medically unsuitable under the scheme.

It must be borne in mind by doctors that this service is intended solely for the admission of acute and emergency cases. For the purpose of the service the definition of an urgent case will be one that requires immediate medical or surgical treatment. Fever cases will only be dealt with on behalf of such voluntary hospitals as specialize in fevers—for example London Fever Hospital.

### The Working of the Scheme

It is not proposed at this stage to go into the detailed working of the scheme but a rough outline can be given as a general guide. The service will obtain a report of vacant beds from all hospitals at stated times of the day and this will be recorded on an indicator board so that whenever a doctor rings up it will be possible to tell him with certainty if and where a suitable bed is available and promptly to book an available bed at such hospital as he may choose. The service will when fully in operation be open throughout the twenty-four hours but in the early stages while working experience is being gained from 8 a.m. to 10 p.m. only during which period it is

estimated that 80 per cent of all emergency calls arise in the night and in both cases be open seven days a week.

A full description of the method of working with instructions as to how to use the service will be published in the *British Medical Journal* in the issue immediately preceding the opening. These doctors who already receive the King's Fund Out-patient Time table will receive a letter advising them when the service is about to open and giving the telephone number which they will be asked not to communicate to the public. In order to avoid receiving calls from the public the number will not be published in the telephone book.

The service has the wholehearted backing of the hospitals and will undoubtedly be welcomed by the public and it as is confidently expected it receives a full measure of support from the doctors there is little doubt that it will soon become an essential service of great value to all concerned.

## PREVENTION OF ACCIDENTS

The National Safety First Association celebrated its twenty-first birthday last week by arranging in London a five day congress with a comprehensive series of lectures and discussions on traffic safety accidents in industrial occupations and the instruction of children in safety measures. The Duke of Kent presented awards for gallantry and long periods of safe driving demonstrations were given of safety training in schools and among other public bodies which participated was Scotland Yard which made its accident map room available to the congress delegates.

### Industrial Eye Injuries

One session was devoted to industrial eye injuries and was addressed by Mr JAMES MINTON of the Royal Eye Hospital. That hospital he said dealt with nearly 7000 injuries every year most of them of a simple nature but others so serious as to mean the loss of one or both eyes. The Home Office reported every year 6000 industrial eye injuries in the United Kingdom so serious as to require absence from work for three or more days. If reports could be obtained from the out-patient departments of eye hospitals all over the country the number of industrial eye injuries annually might well be found to be 60000 or 100000. About 10 per cent of the blind in this country and an even larger proportion in America owed their blindness to industrial injury. Some large industrial undertakings notably Imperial Chemical Industries the Swindon works of the Great Western Railway and the London Passenger Transport Board which had large safety organizations had shown a noteworthy diminution in eye injuries since these were established. Causes of eye injuries, said Mr Minton might be summed up as (1) neglect of safety provision by employers (2) neglect by workmen to use safety measures when installed. Many workmen engaged on grinding wheels and similar machinery appeared to have a prejudice against goggles. A safety device even better than goggles was the provision of a guard on the machine to prevent injury from flying particles but here again there was neglect or unwillingness on the part of workmen to put the guard in place. Mr Minton showed an admirable film which had been prepared for the Royal Eye Hospital to illustrate its work in dealing with industrial eye accidents and mentioned that the hospital was establishing a museum to illustrate the fact that 85 per cent of eye accidents were preventable and to encourage the use of protective appliances.

### Child Psychology and the Accident Problem

At another session of the congress, over which Sir HENRY BRACKENBURY presided Dr SUSAN ISAACS head of the Department of Child Development Institute of Education University of London gave an address on child psychology and the accident problem. She drew attention to the fact that the peak of accidents to children occurred between the ages of 4 and 7. This was followed by a period of relative immunity and again by a rising rate. Certain factors in the child's

nature contributed to this age variance. The child aged from 4 to 7 was specially liable to accident because at about that age he began to free himself from his habit of clinging to his mother. He also found running much easier than walking, he acquired adventurousness and love of experiment, and was naturally impulsive. At the same time he had no appreciation of the danger he ran and no ability to judge distances, speeds, or space relationships. The child aged from 10 to 15, on the other hand, found it natural to walk rather than to run, was more watchful and cool, and was able to judge by the size and appearance of a vehicle the rate at which it was travelling.

Dr Isaacs said that it was not unimportant also to remember that the small child lived in a world peopled by fairies and ogres whereas the older child lived in a world of reality. The small child was so much influenced by his imaginative notions that he personalized everything, including motor cars and railway engines and he allowed his feelings towards these persons, as he thought them, to govern his actions. A good deal of child behaviour was only to be understood from these complex hidden meanings of objects. The child under the age of 7 had no notion of impersonal happenings or of mechanical causality. Machines were persons to him. The fact of accident proneness in industry was well known but in childhood too the neurotic child or the child with special emotional difficulties was undoubtedly more liable to serious accidents than the normal child. There were certain children whom no amount of teaching could keep safe because their deep impulses were stronger than the effect of any intelligent direction. There would always be children who would seek danger without knowing how dangerous it was. The problem of training children to be safe, added Dr Isaacs, was often treated as if it were part of the general question of obedience. It could not be so solved. The child must somehow be shown that it was not safe to run across the road, he must not be merely forbidden to do so.

## EMERGENCY HEALTH SERVICES IN CHINA

*The following notes are extracted from a report by a visiting Red Cross worker which has been forwarded to us through the courtesy of Dr R Cecil Robertson head of No 2 Unit of the League of Nations Anti-epidemic Commission in China*

### A Grave Situation

During the present hostilities there has been an unprecedented migration of population. Everywhere in the country, in villages as well as cities, utilizing every means of communication, people are coming and going in inconceivable numbers. Soldiers are being moved in millions from one part of the country to the other. There is crowding everywhere, and, being obliged by circumstances to ignore even the first principles of hygiene and sanitation, all kinds of sickness are spreading rapidly and widely. The normal medical services in the most important parts of the country are already disorganized in the attempt to strengthen the army medical service. Many important hospitals, including foreign missionary institutions, have been bombed, or for other reasons had to be evacuated.

The normal health services of the Provincial Governments have had their staff depleted and their funds available for health work reduced. All of this has resulted in a very grave situation where the outbreak of epidemic diseases is a very present danger. The most modern methods of preventive medicine and hygiene are being, and will become ever-increasingly, severely tested to cope with this menace.

### Anti-epidemic Units

In the past the League of Nations has lent considerable aid to China by supplying experts in public health, economic reconstruction and other fields of activity such as highway construction. The sending of the League of Nations Epidemic

Commission is another indication of good will towards China. This Commission consists of a group of experts, internationally known scientists who have had great experience in fighting epidemics. Members of the staffs of the National Health Administration and Central Field Health Station have been assigned to the League Commission in the formation of anti-epidemic units for certain definite areas allocated by the Chinese Government. There are three of these Anti-epidemic Units, each being staffed by a group of health officers, bacteriologists and parasitologists, sanitary engineers, sanitary inspectors, and technicians trained abroad and in the training institute which was lately situated in Nanking.

The work of the Commission during its first three months of operation has been divided into a Northern, Central, and Southern Unit. The Northern Unit under the leadership of Professor Mooser has made a special feature of anti-epidemic action amongst the refugees and troops endangered by small pox and typhus fever. Vaccines have been manufactured and anti-vermin precautions instituted. The Northern Unit is German speaking and the overseas experts are chiefly of Swiss nationality. The Southern Unit is under the leadership of Inspecteur Général Lisnet supported by a group of French scientists. The chief activities in anti-epidemic work have been directed against small pox and malaria. The Central China Epidemic Prevention Unit is under the leadership of Dr R Cecil Robertson with an English speaking group of assistants.

### Precautions against Small-pox, Cholera, and Typhoid

The Central China Epidemic Prevention Unit has made a special feature of reinforcing the various provincial health services besides tackling several special epidemiological problems. The diseases of chief concern so far have been small pox, cholera, typhoid fever, and malaria. Each of the three units has had a Government delegate attached to it by the National Health Administration for the purpose of establishing contact with Government Departments and other executive duties concerned with the auxiliary staff. Each unit has had a number of Red Cross teams attached to it for special work in vaccination campaigns among refugees and other duties. The headquarters of the Central China Epidemic Prevention Unit, with which the League of Nations Unit No 2 co-operates, are situated in the Hunan Provincial Health Administration building in Changsha.

A fine central laboratory was first visited, which is fully equipped to handle the diagnostic and bacteriological work. We were shown a number of ingeniously constructed mobile laboratories for field use including locally made bacteriological incubators and steam sterilizers. The unit maintains a branch laboratory for cholera work at Changteh and a mobile laboratory at Yuenling at present. The cholera situation at various points on the Yuan River basin in Western Hunan was explained to us by the Commissioner. We saw plans for the improvement of the water supply at Changteh by means of a special barge from which water can be collected after purification and chlorination, also other sanitary devices applicable to a campaign against water borne diseases such as cholera.

### An Anti malaria Campaign

In the parasitological laboratory we saw work in progress connected with the examination of thousands of blood films for malarial parasites. These were collected on a recent malaria survey of certain rice growing districts in Pingkian Hsien. A serious situation due to malignant malaria has arisen in these areas during recent years. The population has been reduced by disease and the devastation of the Communist horde. Once rich rice growing districts have been rendered uncultivated wastes. The Government plan to settle refugee farmers in this area, but first steps must be taken to reduce the ever present danger of malaria taking a terrible toll of the incomers.

The League Unit has launched an intensive anti-malarial campaign, which in the first instance consists of the establishment of numerous treatment centres to cure the latent malaria.

in the present population prior to the advent of the breeding of the anopheline mosquitoes this year. In the near future the unit hopes to be able to do further anti-malarial work among the workers on the new railway which is under construction from Hengyang in Hunan to Kweilin in Kwangsi. New railroad construction in China always takes a terrible toll of life from epidemic disease among the workers.

In the sanitation division we observed great resource and ingenuity in devising economical equipment and the utilization of local materials. Delousing shower baths for refugee camps and many other appliances appeared to be of simple and practical construction. Old petrol cans and aerosol drums were being converted into various useful sanitary utensils. We also noted travelling vaccinating kits and needle boxes and numerous other pieces of field apparatus being constructed in the workshops. The unit has a fleet of cars for field work and a number of other cars.

The general impression of efficiency and meticulous attention to detail left one with the feeling that this League of Nations contribution to China is a very real one. The whole-hearted co-operation and enthusiasm which such an international organization displays in tackling the horror of serious epidemic disease are comforting and even the most casual observer feels that an important effort is being made to forestall the development of a very serious situation for China's population in this present emergency.

## STANDARDS OF HOSPITAL CONSTRUCTION

### REPORT OF DEPARTMENTAL COMMITTEE

The committee appointed by the Minister of Health in 1933 to consider questions of construction and maintenance of hospitals has issued its final report.<sup>1</sup> In an earlier report it had dealt with what it called in a not very satisfactory phrase, the acute hospital and the present report deals with what must be termed we suppose the chronic hospital. The committee which consisted of six medical members out of a total of fifteen, discusses the size and apportionment of maternity departments accommodation for sick children, residential institutions for pulmonary tuberculosis isolation hospitals, mental hospitals and mental deficiency colonies and public assistance institutions.

#### Maternity Departments

It is considered that very small maternity departments are not desirable and that maternity services should be so organized that departments of less than twenty lying-in beds are avoided. The lying-in ward unit should contain a maximum of thirty beds, eight beds is to be regarded as the maximum for a ward and the committee is favourably inclined to wards of four beds if they can be planned so as to provide good lighting and ventilation. In a ward unit of thirty beds it is considered that there should not be less than six single bed wards. These single bed wards would be used for 'potentially septic' patients and for emergency admissions as far as numbers would allow. The committee recommends for every sixty lying-in beds the provision of ten beds for ante-natal purposes.

In its previous recommendations for the acute general hospital the committee laid down a standard of thirty beds for a ward unit—that is a group of wards in charge of one sister. In hospitals for chronic cases as treatment is simpler and changes of patients much less frequent, a ward unit may properly contain up to sixty beds. There is much less objection to large wards also in dealing with chronic cases but it is nevertheless necessary to provide to some degree of classification of patients and unless the numbers in each class are large enough to occupy

large wards there should be a sufficient number of smaller wards to admit of proper classification. For separation purposes there should be six single bed wards in a ward unit of sixty beds.

Turning to residential institutions for pulmonary tuberculosis the committee points out that here large wards are undesirable. The proportion of single bed wards varies according to circumstances but generally from about 15 to 20 per cent will be found to be required. Other wards should contain a maximum of six or even four beds. But in such institutions as also in isolation hospitals standards are applicable only to a rather limited extent. It is considered that by joint action or co-operation on the part of local authorities the erection of very small isolation hospitals should be avoided but it is not considered possible to recommend any standard minimum size. The size of the ward unit cannot be standardized by reference to the number of patients who may be supervised by a sister. It must in many cases be determined by the size of the hospital and the greater elasticity conferred by small units. About twelve beds in a ward should be the maximum number but there is much to be said in favour of quite small wards (say of four beds), especially in the case of scarlet fever.

#### The Mental Hospital

Difficult as it is to apply standards to the ordinary general or special hospital, the difficulty is largely increased in the case of the mental hospital. Here the proportion of in-patient patients is very high. Space has to be provided for sitting and dining rooms for fully 90 per cent of the patients resident. In addition to adequate accommodation to care and treatment there must be a reasonable standard of comfort. The majority of the patients may not leave the hospital when they wish to do so and detention may be enforced for long periods. No patient should have cause for a sense of injustice arising from the inadequacy of the accommodation provided. On the question whether there should be separate hospitals for men and women opinion has been found almost universally in favour of a combined hospital for the two sexes. Separate ward units should be made for the following groups of patients: recent and recovering sick, able-bodied trustworthy and working on parole, disturbed and excited, senile and infirm, epileptic, indefinite types. Recommendations are made as to the size of the various rooms. On the size of the hospital as a whole 1,000 beds has been adopted as convenient. At a recent discussion in the Royal Medico-Psychological Association the opinion was expressed that this was too large. The point of view however was that of medical staff considerations. A larger number of smaller hospitals would create more posts of medical superintendent and thus offer more chances of promotion for assistant medical officers.

With regard to mental deficiency colonies a colony of not less than 800 beds represents the practical maximum size which permits of adequate classification of all grades of defectives. It is considered that when necessary authorities should combine to establish colonies of not less than that size. The present standard of day space of 10 superficial feet per patient is a good one but in the sick hospital it is only necessary to provide day space for one-third of the patients under treatment. Recommendations are made as to the numbers of nursing and domestic staff for whom residential accommodation may have to be provided, the area of land required for the colony and the methods of construction and materials.

Some remarks are added about public assistance institutions. There appears to be general agreement among those responsible for providing such accommodation if it groups of small cottage homes are suitable for the industrial areas while larger groups of similar cottage homes or a single large home may be thought more appropriate for old people who have been accustomed to living under urban conditions.

## ANTI-VENEREAL MEASURES IN SCANDINAVIA

BY

MARGARET RORKE, M B, Ch B, M C O G

*Consultant in Venereal Diseases to the Royal Free Hospital  
London*

A Commission on Venereal Diseases approved by Sir Kingsley Wood the then Minister of Health left London on July 12, 1937, to visit Scandinavia. The object was to investigate conditions following notification and treatment of venereal diseases in those countries, is the fall in the number of cases in Scandinavia of recent years had seemed to be striking compared with the number of cases returned to the Ministry of Health in this country as under treatment for venereal diseases.

In the three Scandinavian countries visited—Sweden, Norway, and Denmark—a system of partial or of complete notification of these diseases in common with notification of the other ordinary infectious diseases is in force. It was thought that interest and value would be added to the Commission's report\* by a visit to a country where there was no system of notification. Holland was accordingly chosen for this purpose. The fall in the number of cases under treatment, or at least of acute cases admitted to hospital, in Scandinavia seems to be very marked during the summer months. June, July, and August are the holiday months for the great mass of the people, and a migration to the country during most of this period is an outstanding feature of Scandinavian life. Not only do the rich leave the towns during these months but professional and business people's wives and children to a great extent do so, too, living simply in cottages and tiny bungalows, almost entirely in the open air by day. The working-class population, where possible do the same. Many encampments of tents are seen, where working-class women and children live, and where the menfolk return from work on bicycles in the evening, or, if the encampment is too far distant for that, at the week-ends. This is in accord with what seems to be the disposition of the people generally. Their winters are long and dark and they desire, therefore, to gain the utmost from the sunshine and fresh air during the months of good weather. This is not only for enjoyment, but because they are all "health-conscious" without being in the least neurotic. This attitude towards health matters seems general and applies to venereal diseases as well as to any other illness.

### Attitude of the People

The impression formed is that there is not the same sense of shame and necessity for secrecy as regards venereal disease in Scandinavia as still exists in England. The desire to be cured and to attend for treatment as long as is necessary is quite general. The whole attitude towards sex matters in Scandinavia is "modern" and matter-of-fact. One public health official of a large city has been heard to state that he was strongly in favour of condoms being supplied in automatic machines. "It is late at night when the young people return from the country that they require these things, and the chemists' shops are closed then."

The Scandinavian people as a whole are well educated in all health matters and appear to have the utmost respect for, and confidence in, their medical advisers. This is undoubtedly not only due to the equitable disposition of the patients themselves but is fostered by the prolonged and thorough medical training necessary before qualification. A period of at least eight years as a medical student is the usual time for training, and in addition 'specialists' have to study their subject for some years and to pass examina-

tions in that subject before being accredited in the specialty. This undoubtedly accounts in some measure for the very great confidence shown by patients, though no doubt the knowledge that they are bound to attend till treatment is finished must play some part.

### Clinics for Venereal Disease

In various centres in the cities the polyclinics are arranged not only as departments of hospitals but also in the city itself. In some cases the polyclinics for venereal disease may be situated in large municipal buildings, where child welfare, gymnastics, sunlight therapy, baths, etc. are also in use so that no patient entering the building would be obviously attending the venereal department. In some places also smaller polyclinics are situated in flats in ordinary blocks of business flats, and again, save to other patients in the waiting-rooms, it would not be obvious on entering the building that the patient was attending for the treatment of venereal disease.

Almost without exception these clinics are modern in equipment and furnishing, and spotless with white paint (even benches being white enamelled). Flowering plants give a gay air and add a domestic touch. The medical, nursing, and clerical staffs are quick, efficient, and friendly. The waiting patients in turn are ready to spring up and go in immediately a light or a bell indicates that the doctor or nurse is ready for the next patient. This, so far as women at least are concerned, is a welcome change compared with conditions in England, where so often valuable time is wasted by patients not being ready when called upon.

### Treatment

The treatment of gonorrhoea does not compare favourably with that in the teaching hospitals here, but the tests of cure in Sweden and Denmark are prolonged and are undertaken at long intervals after "cure" is believed to have been achieved, and so good results are obtained. In this, of course, the element of compulsion no doubt plays a part in the patients' ready acquiescence when called upon to attend. The treatment of syphilis seems on the whole to be more protracted than in this country, but less arsphenamine is used. Almost continuous bismuth therapy for the whole of the second year of treatment is the usual rule in cases of early syphilis with persistently negative serological tests after two synchronous courses of bismuth and arsenobenzol. Again, patients accept the necessity for investigation of the cerebrospinal fluid, and appear to attend on call when required years later for a lumbar puncture if a pathological cerebrospinal fluid had been found earlier, even though the patient now called upon felt well and free from symptoms. In conclusion, the success of Scandinavian methods seems to depend, as elsewhere on three factors: a well-educated and willing patient, an efficient and kindly doctor, and facilities for treatment readily obtained in pleasant and accessible surroundings.

\*\* The Commission on Venereal Diseases appointed by the Minister of Health in 1937 consisted of Colonel L. W. Harrison and Mr. Dudley C. L. Ward of the Ministry of Health, Dr. T. Ferguson, Deputy Chief Medical Officer of the Department of Health for Scotland, and Dr. Margaret Rorke. Its report, which was published on June 3 by His Majesty's Stationery Office, will receive more detailed notice in a future issue of the *Journal*.

The jury consisting of Dr. Ch. Achard, Professor Urbain Professor M. Lisbonne, and Dr. Devraigne assembled in Paris on May 18, decided that the Prize for Local Immunity shall not be awarded this year. In consequence its amount will be added to that already in hand which will thus attain the sum of 30 000 francs. MSS must reach *La Biographie* 5, rue Paul Barruel, Paris, by February 15, 1939, at the latest.

## Reports of Societies

### INCIDENCE OF TONSILLECTOMY IN SCHOOL CHILDREN

At a meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine on May 27, Sir ARTHUR MACNALLY, presiding, a paper was read by Dr J. ALISON GLOVER on the incidence of tonsillectomy in school children.

Dr Glover said that the rise in the incidence of tonsillectomy was one of the major phenomena of modern surgery. It had been estimated that 200,000 of these operations were performed annually in this country and that tonsillectomies formed one-third of all operations performed under general anaesthesia in the United States. He presented a table showing the number of tonsillectomies on public elementary school children officially recorded annually for London and for England and Wales respectively. A few of the years each typical of his immediate period might be selected.

	London	England and Wales
1919	11,517	42,674
1924	8,051	29,474
1929	17,186	97,518
1934	9,715	73,252
1937	10,125	74,317

A considerable fall in the operation rate took place in 1932 and continued until 1935 in England and until 1936 in London, the rate was now rising once more.

#### Geographical and Age Distribution

Many attempts to assess the after-effects of tonsillectomy, Dr Glover went on, lost much of their value because they gave no precise information as to the age of the children at operation. The period of highest incidence was between 5 and 7 years, a time of great change alike in the oral cavity and in the general development of the child. Was it not possible that many of the operations performed at this age of rapid development removed tonsils which were enlarged physiologically or in response to their protective function? Might not some of the improvement ascribed in such cases to tonsillectomy be really due to physiological changes which normally took place at this stage in the child's life?

Turning to geographical distribution Dr Glover showed how the operation rates differed in various parts of the country. For all England and Wales the average operation rate was 17 per cent, but in six areas (the Stoke of Peterborough, the county of Rutland, the boroughs of Blyth, Wrexham and Bexhill and the urban district of Abertillery) it was more than three times the average rate. Many areas showed more than twice the average rate. On the other hand, four counties, four county boroughs, eleven boroughs and one urban district had rates less than one-third of the average. A child living in Rutland was nineteen times more likely to undergo tonsillectomy than one living in Cambridgeshire. An Enfield child was twenty times more likely to have the operation than one in Hornsey. A child living in Bexhill would seem to enjoy climatic and cultural advantages at least equal to those of a Birkenhead child, yet he was twenty-seven times more likely to be submitted to operation.

#### Social Incidence and Mortality

The social incidence of tonsillectomy was the most puzzling feature of its aetiology. He quoted the recently published report of the Schools Epidemics Committee of the Medical Research Council, which gave the following

information relating to sixteen large public boarding schools for boys and nine for girls. When the inquiry began in 1930 32 per cent of boys and 43 per cent of girls had had their tonsils removed. In every subsequent census these proportions of tonsillectomized pupils increased, and at the end of the inquiry the boys' school with the highest proportion of tonsillectomized pupils showed 70 per cent of all boys in the school tonsillectomized, the school with the lowest proportion had 37 per cent. In the girls' schools the highest proportion was 63 per cent and the lowest 42 per cent.

Finally Dr Glover discussed the mortality from tonsillectomy in children under 15 years. The Registrar-General's statistical review for 1935 included a reference to this mortality for the years 1931 to 1935. Enlarged tonsils and adenoids were given as the cause of sixty deaths over the five years and tonsillectomy without specification of the disease for which the operation was performed was given as the cause of 313 deaths, 269 of these being deaths of children under 15. From the Registrar-General's review and from information supplied by Dr Percy Stocks it appeared that during the five-year period 1931 to 1935 the annual average of deaths from tonsillectomy in children under 15 was eighty-five and this was probably a conservative estimate.

#### General Discussion

Sir ARTHUR MACNALLY said that he had been convinced for a very long time that too many tonsillectomies were done among school children. One clinic had remarked that when they entered their surgeons' found that the supply of juvenile tonsils was diminishing, the standard of the adult. That, however, was unjustified criticism. Many practitioners who perhaps did not realize the benefit of reading the Board of Education reports felt that they were doing the best for their patients in recommending removal of the tonsil and this feeling had spread to parents. He was sorry that Dr Glover had made no reference to the pressure of parental opinion in the more expensive and exclusive schools.

Dr W. H. W. ATTLEE said that at a school in which he was interested something like 50 per cent of the new boys had had their tonsils enucleated. Thirty years ago the proportion was something like 20 or 30 per cent. Undoubtedly the general school health was better now than formerly, but he thought this could be accounted for by improved hygienic measures rather than by the greater incidence of tonsillectomy.

Mr T. B. LAYTON said that as early as 1911 he came to the conclusion that the number of tonsil operations was excessive. On resuming his civil practice after the war he became more and more conservative in this respect. It seemed to him that there was an overwhelming evidence that the subepithelial lymphatic glands of the upper respiratory tract formed one of the child's first lines of protection during the time it was developing acquired resistance. Of these glands the tonsil was the largest and was slightly different in structure from the others and he believed it to be the most important of the protective mechanisms. If a person had had three attacks of tonsillitis which seemed to be due to organisms residing in the tonsils—not acquired from without by droplet infection—he would not admit that tonsillectomy was a gamble. One was more likely to get a good result from that operation than from any other in surgery. But without such an indication he did not think one could ever be certain that the advice to have the tonsils removed was really productive of good result. At least as much time should be given to making the decision as to operation as was given to the operation itself and he refused to do tonsil operations in children quickly, twenty minutes being his minimum. He thought it likely that not very much harm was done in removing tonsils from children on the well-to-do living under conditions of good hygiene but irreparable harm could be done by removing the lymphoid tissue of children living under a bad regime. For years he had followed the rule that the tonsil of a child under 5 should never be removed unless the evidence in favour of removal was over-

whelming and subconsciously his age limit was going up and up. In tonsillectomy as practised in the eighties of the last century the children operated on were usually aged from 11 to 14. The nomenclature had been retained, but the age at which operations were customarily done had been altered. Among other contraindications he refused tonsil operations during the winter. He also would not operate on a child because of recurring colds, to do so was to invite a bad result. In chorea he dreaded taking out tonsils for fear of making the condition worse. One often heard of tonsillectomy being performed to cure otitis media and he was willing to admit that in a certain number of cases it was a proper operation but he was absolutely opposed to routine tonsillectomy in this condition.

Mr E D D DAVIS said that tonsillitis might be primary or secondary. A primary tonsillitis was derived by one patient from another and from extraneous causes but there were a certain number of cases which followed the extraction of teeth or a septic operation on the nose. He believed the ear, nose and throat surgeon selected his cases very carefully, but a certain amount of pressure was brought to bear on him by the family practitioner.

Dr L G GLOVER recalled that many years ago he was medical officer to a convent school attended by children of the poorer class. He was accustomed to examine the children every quarter. He divided the tonsil cases into three classes: those which must be operated on, those which might be operated on, and those which need not be operated on. He told the nuns that the children in the first class should be operated on but nuns were not keen on operations and the bulk of the children were not subjected to operation. After a year or eighteen months he found that these children could be placed in the class that needed no operation.

Dr PERCY STOKES said that Dr Glover had estimated that about 20 per cent of elementary school children by the time they were 14 had been tonsillectomized. He supposed that taking the whole child population up to that age, the proportion might be 25 per cent. In an April issue of the *Public Health Reports* of the U.S.A. Collins gave some statistics of the frequency of these operations in the United States. They related to a sample of about 40,000 individuals in eighteen different States coming from town and country and representing all types of social classes. Over four years the families were visited in their homes and detailed records were kept of the operations. It appeared from the tables of operation rates at each age that if the rates of tonsillectomy had been maintained in a group of children growing up from birth to the age of 14, 54 per cent would have been tonsillectomized by the time they reached their fourteenth birthday. That figure might be taken as roughly comparable with the 25 per cent in this country. The American figures also showed the rate to be greatest in the cities and in families with the largest incomes. Dr R P GARROW suggested that maternal anxiety was an important factor in the demand for tonsillectomy.

The Chengtu Eye, Ear, Nose, and Throat Society, the first society in China representing jointly those practising in ophthalmology and otolaryngology, was organized at the Eye, Ear, Nose, and Throat Hospital in Chengtu, West China, on December 14, 1937. The following officers were elected: President, Dr Eugene Chan, Vice-President, Dr Robert A. Peterson, Secretary, Dr C C Teng, M.D., and Treasurer, Dr C R Peng. The members of the society are derived from the departments of ophthalmology and otolaryngology of the West China Union University of Chengtu, West China, of the National Medical College of Nanking, and of Cheeloo University of Tsinan, Shantung, and from practitioners specializing in these fields in Chengtu and other centres in West China. The transfer of medical schools with their faculties and students from the war zone in East China to Chengtu in West China has created there a unique centre of medical teaching and clinical activity.

## OCCUPATIONAL DERMATOSES

The summer meeting of the Association of Industrial Medical Officers was held this year in Nottingham on May 12, when a discussion on the occupational dermatoses was opened by Dr H S WALLACE of the Nottingham General Hospital, who was present by invitation, with the chairman of the association, Dr L P LOCKHART in the chair.

Dr Wallace described briefly the structure and functions of the skin, stressing its protective and detoxicating properties. He mentioned the difficulties experienced in distinguishing between skin reactions due to internal and external irritation and discussed the value of the patch test. Dermatoses, he said, were caused by mechanical, thermal, ictinic, chemical, and microbic agents. In relation to the industrial side of the problem he considered that the true occupational dermatoses came under three headings—namely those due to strong irritants, those due to idiosyncrasy and those caused by the repeated action of a mild irritant. The industrial skin lesion began as a rule on the part where exposure was greatest, and might thereafter spread to other parts. It cleared up quickly on giving up work, but might return if a long convalescence was not allowed. The prevention of industrial dermatitis could be brought about by (1) selection of workers, (2) adequate protective methods, and (3) cleanliness. In discussing treatment Dr Wallace referred to the value of low carbohydrate and fat diets, to the exhibition of alkalis and calcium, and to the application of lotions, creams, and pastes. No greasy ointments, he maintained, should be used except in chronic old-standing cases. He mentioned also methods of desensitization by protein injections and by autohaemotherapy.

On May 13 members of the association visited the factories of Messrs Boots Pure Drug Company Limited at Nottingham and Beeston, at the invitation of the company, and were entertained to luncheon by the chairman, Lord Trent.

## EXPERIMENTAL ALLERGY

At a meeting held at the Sims Woodhead Memorial Laboratory, Papworth Village Settlement, on May 19, Dr WALTER PAGEL gave a demonstration on the allergic tissue reaction and the allergic diseases.

Dr Pagel showed that the reaction of the allergic tissue differed from that of normal tissue not only in the intensity of the inflammatory process and the time of its appearance but also in certain qualitative features. Characteristic of the allergic tissue reaction were, for instance, hyaline nodules with peripheral mononuclear cell proliferation reminiscent of rheumatic nodules and intensive infiltration with eosinophilic cells. The allergic theory of rheumatism was then discussed. Experimental muscular rheumatism produced by the intramuscular injection in rabbits of 1 c.c. of a muscular antiserum (serum from guinea-pigs treated with suspensions of muscular tissue from rabbits) was shown. The intravenous injection of pig serum and caffeine (5 to 10 c.c. of a 10 per cent solution) in rabbits sensitized against pig serum led to a localization of the allergic reaction to the cardiovascular system. In the myocardium, mononuclear cell nodules developed resembling those seen in certain human conditions, such as chronic septicaemia or polyarthritis, and in the aorta extensive atherosclerosis was observed. The work done in conjunction with Dr Paul Kallos (Stockholm) supported the theory that allergy was a factor in the pathogenesis of conditions related to rheumatism.

## Local News

### ENGLAND AND WALES

#### Empire Rheumatism Council

Lord Horder chairman of the Empire Rheumatism Council gave an informal luncheon on May 26 for the purpose of wishing success to the first three Research Fellows appointed by the Council—namely Dr C B Dyson Dr H J Taylor, and Dr W S Tegner. In introducing the guests Lord Horder said that the gathering was intended to bring together three groups of persons interested in the problem of rheumatism research and treatment first of all the three Research Fellows who represented the immediate spearhead of the movement then a number of benefactors whose munificence had made the appointments possible, and finally the officers and members of the Council itself. The first of the Research Fellows Dr Dyson had been for the past seventeen years engaged in research work in the pathological department of St Mary's Hospital. He would carry on his work for the Council at the Alexander Maclean Laboratory Hospital of St John and St Elizabeth London at the British Red Cross Clinic for Rheumatism London and at St Mary's. Dr Taylor who since 1928 had been engaged in research work at the St John Clinic Plymouth would also work at the Alexander Maclean Laboratory, and at the St John Clinic and at St Stephen's Hospital. Dr Tegner who had been chief assistant at the British Red Cross Clinic since 1936 would carry out work in a different category from the other two he was leaving London as holder of the Sir Alexander Walker Travelling Scholarship to study and report on the methods of treatment followed in the chief rheumatism clinics of Europe and North America. The whole purpose of the movement was intensive research in the laboratory and by the bedside into the causative factors of rheumatic disease. Each of the Research Fellows then briefly addressed the company saying with what expectations they started upon the enterprise. Sir William Willcox one of the trustees of the Council proposed the health of the benefactors mentioning in particular Mr J Spedan Lewis Mr H Gordon Scliffidge Sir Benjamin Cohen Sir Alexander Walker Colonel Gretton M.P., Mr Alexander Maclean and Sir Joseph Burn. Mr Maclean and Sir Joseph Burn responded the latter, who is general manager of the Prudential Assurance Company remarking upon the loss of industry represented not only by the actual sufferers from rheumatic disease but by those in their family—daughters particularly—who were expected to give up their own work to attend a crippled parent.

#### The Modern Hospital on Exhibition

An exhibition of photographs and other illustrations of modern hospitals in the United Kingdom and abroad has been arranged by the Royal Institute of British Architects at the Building Centre New Bond Street, London. The large architectural plans need an expert eye to read them, but the scale models and the excellent photographs are instantly to be appreciated. They certainly bring out the striking contrast between hospitals old and new. The old hospitals were very often built with few ideas as to planning and none at all as to beauty and with the extensions that have been necessary from time to time they have become amorphous and exasperating constructions in which one loses one's way and is revolted by ugliness at every turn. The modern hospital on the other hand has a beauty in its mere plan without any adornments of which the architect is properly sparing. The hospitals of which plans are shown include the new Westminster the buildings of St Bartholomew's, South West Middle-

sex Fever Hospital the new isolation block of London Fever Hospital St Helier's Hospital Surrey the Kent and Canterbury Hospital a model of the Tuberculosis Hospital Sully Cardiff and the design for the reconstruction of Great Ormond Street Hospital for Sick Children. A new Hospital and Medical Section has been added to the Building Centre to provide medical men architects and hospital authorities with means for obtaining specialized information on all matters connected with the building and equipment of such institutions. One feature of the section is an up-to-date library of hospital plans contributed by architects from all parts of the world. These plans are available for consultation by those professionally engaged in any form of hospital work.

#### Tuberculosis Conference in London

The following are the subjects for the twenty-fourth annual conference of the National Association for the Prevention of Tuberculosis to be held in the Great Hall British Medical Association House Tavistock Square London W.C.1 on June 30 and July 1 and 2. (1) The development and organization of anti tuberculosis activities in rural areas. (2) The family and tuberculosis—the discovery and protection of contacts in a tuberculous household. (3) The control of tuberculosis in tropical and sub-tropical regions. (4) The mental aspects of tuberculosis. (5) How tuberculosis affects the mental life of the normal person. (6) How the mentally disturbed patient is affected by tuberculosis. Practitioners interested in any of the above subjects and wishing to attend any part of the conference may obtain an invitation on application to the Secretar General N.A.P.T. Tavistock House North Tavistock Sq are London W.C.1.

#### Portsmouth Health Congress

The Royal Sanitary Institute in the preliminary programme of the Health Congress which is to be held at Portsmouth from July 11 to 16 announces that among the subjects to be discussed at this year's congress are the following the future of the general hospital the defects found in school entrants and the steps that might be taken to effect their remedy before the beginning of school life behaviour and nervous disorders in children clinics for the pre-school child the food manufacturers contribution to public health the Food and Drugs Bill 1937 meat and food inspection the Tuberculosis (Attested Herds) Scheme air raid precautions propaganda and the hygiene of indigenous races in the Tropics the health of the worker and the duration of incapacitating sickness. The congress will have as president the Earl of Bessborough and already 860 official delegates have been appointed by Government Departments foreign and Dominion Governments and municipalities local authorities etc in Great Britain. At the Health Exhibition arranged in connexion with the congress the exhibits will include foods sanitary appliances and appliances illustrating municipal activities and hygiene in the home.

#### British Orthopaedic Association

On the first day of the spring meeting of the British Orthopaedic Association a dinner was held at the Langham Hotel with the president Mr Naughton Dunn in the chair. In proposing the health of the British Orthopaedic Association Mr H S Souttar said that he shared with them all a great regard and affection for the founder of the association the late Sir Robert Jones whom he well remembered meeting in 1910 at Netley. It was to him that they owed the creation of the B.O.A. and the position that orthopaedic surgery held to day. He was glad to notice that there were present that night representatives of the orthopaedic art from all the northern countries of Europe, and he congratulated the British Orthopaedic Association on securing their attendance. Mr Souttar then paid a graceful tribute to Mr Naughton Dunn and

ended his speech by sustaining his now well-known reputation as a raconteur. In reply, the President recalled the first meeting of the British Orthopaedic Association at Roehampton Hospital and the late Mr Muirhead Little, who was their first president. He had, he said, received letters of good will from Professor Osgood and from Dr Goldthwaite of Boston. In proposing The Guests Mr Harry Platt classified them neatly and according to the usual device of the surgeon into three groups: (1) the personal guests of individual members; (2) the co-workers in the cause of orthopaedic surgery; and (3) guests from over-seas. In according a special welcome to colleagues from Denmark, Norway and Sweden, Mr Platt said they all had very pleasant memories of the meetings held last year at Copenhagen and Stockholm and they had had it in mind to organize the present meeting in honour of their guests on that occasion. The Scandinavians he remarked, had been here before—as pirates who in history books were euphemistically described as Vikings. He coupled the toast with the name of Professor Wildenstrom, who in reply said that the Vikings were here again and this time as friends. He then invited the Scandinavians present to stand up and drink to the welfare of the British Orthopaedic Association, which they did, punctuated with lusty shouts of welcome. After that Professor Maffei of Brussels said a few words in both French and English.

#### The London Hospital's Needs

In 1940 the London Hospital will celebrate its bicentenary. The chairman, Sir William Goschen, announces that a survey of the hospital's vital requirements has lately been made by the medical and surgical staff, who have recommended as major needs the building and equipping of a modern x-ray department, 'remodelling of the operating theatres, the establishment of a fracture clinic, extension of the laboratories, ear, nose, and throat wards, adequate accommodation for septic cases, improvements to the children's wards, a new dental department, and an extension of the nurses' home. The cost of carrying out this programme is estimated at £270,000, and to this must be added £60,000 for general funds. At a festival dinner, held at the Mansion House on May 25, a gift by Lord Nuffield of £10,000 was announced, making £46,000 already received for the extensions and improvement scheme. The Duke of Kent said from the chair that Queen Mary had asked him to give a cheque for 200 guineas as a mark of her interest in the appeal as President of the London Hospital. The Archbishop of Canterbury, supporting the toast of 'The London Hospital', said that he did so with real personal enthusiasm, having been associated with the hospital during eight hard and happy years as Bishop in the East End.

#### Newcastle Conference on Child Nutrition

On May 14 the Children's Minimum Council held in Newcastle-upon-Tyne the second of its provincial conferences on child nutrition. Over six hundred people, including delegates from 214 organizations of all kinds in Northumberland and Durham, enthusiastically supported resolutions calling on the Government to ensure better food standards for mothers and children. All the political parties were represented, and delegates came from twenty-three local authorities, from trade unions, religious, social, and educational bodies, women's guilds and institutes, teachers and medical people. The Lord Mayor of Newcastle opened the conference and presided over the first session. The principal speakers were Professor V. H. Mottram, on 'Food as the Foundation of Fitness,' and Miss Eleanor Rathbone, M.P., on 'The Beginnings of a Nutrition Policy.' Professor Mottram paid a tribute to the research work done by Newcastle scientists: 'It is the mothers and children who suffer most. By the time the children come under the care of the education authorities they are already damaged goods. If we could only feed the children and the expectant mothers we should do

much to produce a decent nation.' Miss Rathbone, chairman of the Children's Minimum Council, explained that the Council was a non-party, co-ordinating body working to improve standards of child nutrition. She urged free milk for all school children, cheap milk for mothers and young children, and school meals to be regarded as a part of the school routine. She pointed out that the number of children receiving dinners had remained practically the same as in 1911. She reminded the delegates of the promise of the Parliamentary Secretary to the Ministry of Agriculture, made during his election campaign in 1935: 'I hope soon to be able to announce a policy under which the cheap milk scheme for school children will be extended to expectant mothers and children under 5. It is our policy to divert surplus food into the stomachs of those who live in our back streets and who are sorely in need.' She urged the formation of a local committee to continue the pressure on the Government through all Northumberland and Durham organizations. Many delegates joined in the discussions in each session, several pointing out that increased incomes were the key to better nutrition and another mentioning the difficulties of 'scholarship children, and suggesting that they should all be provided with food and clothes. Dr David Burns, professor of physiology at King's College, Durham University, presided over the evening session.

## SCOTLAND

#### Lord High Commissioner's Visit to Hospitals

The usual round of visits to Edinburgh hospitals was paid last week by the Lord High Commissioner, Sir John Gilmour, representing the King at the General Assembly of the Church of Scotland. At the Royal Infirmary on May 25 Sir John and Lady Gilmour presented prizes to the nurses. In a short address Sir John said that the problem of accommodation was one which caused great anxiety to the governors of hospitals, both on account of difficulty in providing for an increasing number of persons who sought admission, and in finding accommodation for the greater number of nurses who were now required. Conditions of service of nursing staffs were being much improved, and those who knew the self-sacrificing nature of a nurses' work agreed that this improvement was welcome. The following day a visit was paid to the Deaconess Hospital, where the Rev. Dr Fiddes, vice-chairman of the Hospital Board, said that at its opening in 1894 this institution had had twenty-two beds, to-day it was a modern hospital with eighty-eight beds. It was the only hospital in this country founded and entirely supported by the Protestant Church, but it was not in any way a sectarian or even a local hospital. On May 27 Sir John Gilmour addressed the annual meeting of the Edinburgh Foot Clinic, at which Lord Elphinstone, who presided, said that the annual number of treatments at the clinic was now some 22,000.

#### Scottish Health Visitors

The annual conference of the Scottish National Health Visitors Association was held at Aberdeen on May 21, delegates from thirty-two local authorities attending. Dr J. M. Mackintosh, Chief Medical Officer of the Department of Health for Scotland, pointed out that the decline in the infant mortality rate from 130 at the beginning of this century to 80 at the present time related chiefly to infants after the first month of life, about half of the infantile deaths every year occurred during the first month of life. The time for taking a child to the welfare centre depended upon many factors, but as a rule this should be about the end of the first month of life when home routine had been re-established. Dr James A. Stephen, medical officer for mother and child welfare work in

At fifteen drew attention to the changes in the rates of death among infants. The death rate from diseases of the digestive system had fallen from 47 to 17 while that from prematurity had increased from 29 to 31 and that from bronchitis and pneumonia had fallen from 24 to 20. The significant fall in deaths from digestive diseases was due largely to the better education of mothers by health visitors in the homes and at child welfare centres. Lady Leslie Mackenzie Edinburgh said that in some places caravans took health visitors to the scattered homes of mothers in country districts; she believed in this was a movement which ought to be encouraged by medical officers of health.

### Scottish Housing Conference

At the annual conference of the Scottish National House and Town Planning Council held in Stirling last week Mr H J Scrimgeour Wedderburn Under-Secretary of State for Scotland addressing some 200 delegates from local authorities said that Royal Commission about twenty years ago estimated that Scotland required 200,000 houses to solve her housing problem. Since then over 280,000 working class houses had been built in this country at an annual cost to the Exchequer of over £2,000,000. These new houses represented in the aggregate a city of about the size of Glasgow but they had enabled only about one quarter of the whole population to be rehoused in modern well equipped dwellings. Present requirements were still estimated at 200,000 new houses but he believed that when these were built they would be found not to be sufficient. He described the use of timber which made good permanent houses that were likely from the experience of Canada and Sweden, to last considerably longer than a house of the same kind built of brick. The Department of Health he said was prepared to approve a subsidy at the usual rates for such timber houses and some twenty four housing authorities in Scotland were considering the use of wood. The city architect of Edinburgh discussing alternative methods stated that Canadian red cedar had until recently been too costly for ordinary use but as Americans were now using their own timber Canadian lumber had fallen to a price which afforded a great opportunity for its employment in this country.

## FRANCE

[FROM OUR CORRESPONDENT IN PARIS]

### A Windfall for the Academy of Medicine

Thanks to the generosity of Madame Jansen the Academy of Medicine is the richer by some five million francs. With the franc at eight to a shilling this gift may not seem very imposing in terms of sterling but it is most welcome just because of the depreciation of the franc for the Academy has in its gift many prizes and scholarships whose cash value has become derisory as the franc stands at present. It is therefore probable that this latest windfall will be devoted not only to new prizes but also to infusing new monetary life into old ones.

### Hereditary Factor in High Blood Pressures

On April 12 Dr G Richard of Royat les Bains presented to the Academy of Medicine a study of the influence of heredity on hyperpiesis. After concluding from the literature of this subject that there is a history of hyperpiesis in the ancestry of some 70 per cent of hyperpiesics he proceeded to record his latest observations of 1,836 cases. He found evidence of hyperpiesis in the ancestry of 79 per cent and he was able to confirm, up to a certain point the observation of von Budy who noted this peculiarity about hyperpiesis—

namely that the condition is often transmitted to the sons rather than to the daughters if the father is a hyperpiesic and vice versa for the distaff side. It would also seem that the site of a hyperpiesic lesion is apt to be identical for the various members of the same family. Dr Richard has come to the really alarming conclusion that the offspring of parents both of whom are hyperpiesics have only sixteen out of a hundred chances to escape hyperpiesis themselves. This chance is forty-three in a hundred when only one parent is a hyperpiesic. It may therefore be advisable to discourage the marriage of those whose families have a bad record of hyperpiesis on both sides.

### Tuberculosis Campaign Since 1918

The following table will show at a glance how much has been done between 1918 and 1936 to provide the tuberculosis victim with sanatoria and hospital nurses etc.

	1918	1936
Depression	70	43
Healed cases	113 beds	— 4 beds
At present	—	374
Sanatoria	195 beds	1346
Private	—	130
Health centres	—	40
Recreation	—	57
1. Private	—	70
2. Public	660	800
Sanatoria	—	20
Sanatoria	70	2000 for tuberculosis

In the period under review the number of sanatoria for pulmonary tuberculosis has risen from nine to 138 the number of hospital sanatoria from none to twenty one surgical sanatoria from five to fifty five and preventoria from none to 225. One of the most remarkable achievements is the foundation of as many as twenty six schools of visiting nurses there was nothing of the sort in 1918. The Grancher system of taking children from tuberculous homes and putting them in healthy homes with foster parents has it will be seen grown greatly in favour since 1918.

### Medical Examination of Motor Drivers

In an earlier letter (*Journal* April 16 p. 869) reference was made to a resolution recently adopted by the Academy of Medicine in favour of medical examination of all motor drivers in the hope that it would do something towards reducing the number of motor accidents. This resolution has not enjoyed a very good press. Though the Latin temperament is said to be as hostile to compromise as the Anglo-Saxon temperament is addicted to it there is a chance of the suggestion being adopted that the medical examination should be reserved for the drivers involved in road accidents which involve the arm of the law. If all such drivers had to undergo a medical examination which included mental tests conducted by a psychiatrist might not the very prospect of this ordeal induce some caution even into the most rash? To emerge from it branded as a high grade mental defective or with some even more opprobrious term recently invented by the psychiatrists would be to suffer an indignity far greater than any deserved sentence or even term of imprisonment. Apart from this prophylactic action of the psychiatric examination there would presumably be a good prospect of the recklessly inconsiderate driver having his licence cancelled on the strength of the psychiatrist's report.

## Correspondence

### Treatment of Anterior Poliomyelitis

SIR—My attention has been drawn to a letter from Dr E A Buckley on the above subject in the *Journal* of May 21 (p 1130) in which he makes specific reference to the opinions of "orthopaedic surgeons and others" who apparently have been closely identified with the treatment of cases at the LCC Queen Mary's Hospital Carshalton. The treatment of these cases of poliomyelitis at Carshalton by Sister Kenny's methods is under the constant supervision of an advisory committee of some of the best-known orthopaedic surgeons and neurologists in London. It is hoped that some time in the autumn a report will be submitted to the London County Council from the advisory committee as well as from the Council's own permanent medical and surgical staff. In the meantime it is only fair to Sister Kenny, as well as the members of the advisory committee and the LCC's own staff, to make it quite clear to your readers that they are not in any way responsible for the statements made by Dr Buckley. In fact, I am informed that none of them has ever seen or heard of Dr Buckley before his letter appeared in the *Journal*—I am, etc.,

FREDERICK MENZIES,  
County Hall London SE 1 Medical Officer of Health, LCC  
May 27

### Nutrition of Denmark During the War

SIR—Dr Johanne Christiansen wrote to the *Journal* of May 28 (p 1174) a letter to correct misunderstandings which may have arisen from a reference by Dr Alfred Jordan to the rationing of foodstuffs in Denmark in 1918.

Those who are interested in this remarkable experiment in a whole national diet will find a description of it in the *Deutsche Medizinische Wochenschrift* of March, 1920. This article published in a medical paper of the highest repute and from the pen of Dr Hindhede, himself at the time of the experiment food adviser to the Danish Government, gives a different story from that of Dr Christiansen. The diet was a lacto-vegetarian one with a modicum of meat and alcohol. It was in fact a diet not unlike that of the exceptionally healthy Hunza people, to whom Dr Jordan refers in his letter.

Dr Christiansen is not himself free from creating "misunderstandings." I will take but one example for correction. He writes of the "vegetarian faddism of Hindhede." Dr Hindhede himself wrote in the above article "I am not in principle a vegetarian, but I believe I have shown that a diet containing a large amount of meat and eggs is dangerous to health. That, taken generally, may be untrue. In my opinion it ignores the striking health of such Danish subjects as the Polar Eskimos and the Faroe Islanders, but it is not vegetarian faddism—I am, etc."

G T WRENCH M D

### Incidence of Permanent Disability after Industrial Injury

SIR—Near the end of last year (*Supplement* December 18, p 367) you published a memorandum on rehabilitation centres for injured workmen. It was there stated that it should be possible to restore 95 per cent of the victims of industrial accident to their former working capacity. Permanent disability was thought to be inevitable in no

more than about 5 per cent of cases. In the course of subsequent correspondence this figure was challenged, and the incidence of permanent incapacity was put as high as 30 per cent.

With the object of producing definite evidence I carried out a statistical inquiry into the end-results of accident cases treated in the six-month period ending December 31, 1937, at the fracture clinics at Walton Hospital, Liverpool. The accompanying tables show the results of this inquiry. The total number of cases investigated (439) represents only such persons as were in employment at the time of the injury. Children, housewives, unemployed, and pensioners were excluded. The point with which I was chiefly concerned was to find the proportion of injured persons who eventually returned to the same occupation. Every case has been investigated, either by letter or interview, and the patient's statement as to the actual date of return to work has been accepted in estimating average disability periods.

TABLE I—In patients

Average	No of Cases	Average No of Days in Hospital	Average No of Subsequent Out-patient Attendances	Average Time off Work	Patients Returned to Work by April 1 1938	Died	Still Attending April 1 1938
Accidents at work	66	14.81	3.29	54.3	57	2	7
Road traffic accidents	50	13.28	4.61	56.7	35	7	8
Other accidents	45	12.58	3.73	53.2	36	4	5
Total	161				128	13	20

TABLE II—Out patients

	No of Cases	Average No of Out-patient Attendances	Average Time off Work (days)	Returned to Work by April 1 1938	Still Attending April 1 1938
Accidents at work	130	3.7	19.02	126	4
Road traffic accidents	31	4.64	30.8	31	0
Other accident	117	5.0	27.5	113	4
Total	278			270	8

TABLE III

Total number of employed patients treated during six months ending December 31 1937	439
Returned to work by April 1 1938	398
Dead	13
Patients still in hospital or attending as out patients by April 1 1938	28

Briefly the figures show that by April 1, 1938, of 439 employed persons treated during the six-month period from July 1, 1937 to December 31, 1937, 398 had returned to work, while forty-one (9.7 per cent) were either dead or still attending. Of the twenty-eight remaining in hospital or attending as out-patients I consider that thirteen will return to their former employment. If these expectations materialize the ultimate result will be that the proportion of persons suffering incapacity sufficient to prevent return to former employment is 6.4 per cent, this figure including 3 per cent dead.

I have no idea how my figures will compare with those of other surgeons. In view of the rather depressing estimates given by some of your correspondents, I am fairly pleased with the high proportion of patients who returned to their previous occupation. In regard to their disability periods there is no doubt that these could be improved.

considerable. Had I used figures expressing the date of or my own opinion as to fitness for full work the disability periods would have made a better showing, but entirely apart from this consideration, my investigation of the case records has led me to feel more strongly than ever that the establishment of rehabilitation centres would be a paying proposition to those upon whom falls the expense of caring for injured persons.

Every surgeon who comes into contact with persons injured during the course of their employment cannot fail to be impressed by the number whose return to work is delayed by the absence of facilities providing graduated activities leading to full manual labour. Organization in fracture clinics ensures that the patient shall be cured of his injury as quickly as possible. This is achieved by the provision of a record and appointment system which arranges that the injured person shall be brought before a trained surgeon at frequent intervals and with infallible certainty. A patient who fails to attend at the clinic on the due date receives within forty-eight hours a postcard inquiring the reason. I believe that this simple device plays a great part in securing the full co-operation of the patient up to the time of his cure.

But when the injury is cured there comes the period which must elapse before he is ready for work. Neither organization in fracture clinics nor massage departments can do anything to shorten this period. The rehabilitation centre envisaged in the report of the committee appears to provide exactly what is required to help those surgeons who are continually striving to reduce periods of disability to the minimum. It will improve results by shortening the period between "cure of injury and fitness for work," and it will bring closer the two dates which now are commonly far apart—that on which the surgeon believes and that on which the patient also believes he is fit for work—I am, etc.,

Liverpool May 23

W S DIGGLE,  
MChOrth FRCS

### Pancreatic Extract in Graves's Disease

SIR,—It is now eight months since there appeared in the *Journal* my article on the treatment of Graves's disease with pancreatic extract (October 2 1937, p 660). The recent paper by Mr Peter McEwan (May 14 p 1037) and Mr Cecil A Joll's letter (May 21, p 1123) have prompted me to make another appeal to the medical profession—this time included—at least to try the effect of pancreatic extract and small amounts of iodine in all cases that have the "thyrotoxic mask." Medical treatment is always bound to be slow in cases of endocrine imbalance and we cannot hope to produce the spectacular effects of thyroidectomy but as Mr McEwan writes—all are agreed that operative treatment of a gland so valuable as the thyroid is to be regretted and hope that medical research may find a better way. I am convinced as a result of the treatment of toxic goitre since 1931 with pancreatic extract that a remedy is at hand more especially in the goitrous condition is recognized early.

In a series of thirty-five cases of toxic goitre treated by me the results would bear favourable comparison with the operative results mentioned in Mr McEwan's paper. One certain fact admitted by several of my colleagues—that the diarrhoea of Graves's disease is distinctly helped by the oral administration of pancreatic extract. In several instances parenteral injections of a pancreatic hormone have entirely stopped the excessive stools and even the goitrous symptoms have gradually improved.

Mr Joll in his letter states that he is often in grave doubt as to whether a diagnosis of thyrotoxicosis is or is not substan-

tiable. This of course my greatest difficulty and I am certain that not unjustifiable criticism could be levelled at some of the cases that I have looked upon as cases of incipient goitre and treated as I thought successfully with pancreatin and alphidine. At all events whether or not some of my cases have only been neurotic the tachycardia tremors pulsation in the neck nervousness and loss of weight have all disappeared with my treatment within a few weeks and almost certainly within months.

With regard to immediate operation in all cases of toxic goitre we are asked to become goitre minded as we are appendicitis minded. Surely this seems too much to ask the general practitioner for in the one case a definitely useless appendage is being removed while in the other the structure in question is essential to the endocrine balance. Again the operation near or thyroidectomy has an effect on the subconscious mind of the patient and the operation is being performed on a person in a highly nervous state. Undoubtedly thyroidectomy has a very important part to play in the treatment of advanced toxic goitre or in the adenomatous forms which often in time become toxic. The surgeon has a very difficult task and it is little wonder that Mr McEwan states that only 67 per cent of his cases were fit for a full day's work.

Practically all forms of toxic goitre must be insidious in their origin and pass through an incipient stage. In none of my incipient cases of the past even years treated early with pancreatin has there been retrogression nor has the syndrome of symptoms manifested itself sufficiently to warrant surgical intervention. In some instances the enlargement of the thyroid has disappeared as also have the marked exophthalmos tremors and tachycardia in fact whatever the degree of the disease was the patient always admits that an improvement set in after the oral administration of pancreatic extract.

One thing is essential—namely, to find some surer method or early diagnosis whether instrumental or biochemical. I feel convinced that the cure of Graves's disease lies in the hands of the general practitioner who learns to make an early diagnosis and begins treatment with pancreatic extract and alphidine or Lugol's iodine in small doses. All cases showing an increased pulse pressure tachycardia nervousness tremors, and pulsation in the neck without necessarily having an enlargement of the thyroid should be looked upon as potential cases of Graves's disease—I am, etc.,

Liverpool May 25

C BAIRD MACDONALD

### Irradiation or Surgery for Cancer?

SIR,—The treatment of cancer by irradiation is receiving an ever increasing amount of notice in the medical press. Constant references to the subject are also occurring in the lay press and the cry is always for radium and yet more radium. The general public is given the impression that all that is necessary to combat the ravages of malignant diseases is a sufficient supply of radium. Brilliant results which have been obtained by other methods are apt to be forgotten and surgery has been driven into the background. Is this fair to the surgeon or what is much more important to the patient? Irradiation is often referred to as the modern method of treating cancer. Modernity is not always a recommendation, as can be witnessed in the case of music, painting architecture and certain forms of government.

The annual reports of the National Radium Trust and Radium Commission for 1936-7 which reveal statistics of the treatment of carcinoma of the mouth cheek, palate alveolus, tonsils, will be seen when compared with those of radical surgery, so far as immunity from recurrence is concerned, to show retrogression rather than advance. It will be noticed in that report

(c) That histological confirmation of the clinical diagnosis of carcinoma was obtained in less than half the cases—

namely 46.6 per cent. Thus conclusions in more than half the patients reported on are therefore based on clinical evidence only.

(b) A period of three years survival rate was adopted whereas in the surgical statistics, which I shall quote, the period was five years. Although the report concerns radium treatment it seems that surgery was extensively employed, as, for instance two hundred block dissections of the neck were carried out with an operative mortality of 7.2 per cent. Allowing that all the cases treated would have been confirmed by biopsy to be carcinoma, we find, on comparing the results of irradiated cases with those published by Mr. Norman Pitterson in the *Lancet* of September 22 and 29, 1936, where surgery was employed and all cases confirmed by biopsy, that the survival rate of the latter is markedly better.

A short reference to the statistics shows

(i) For carcinoma of the hard palate treated by irradiation there is a survival rate of 28.6 per cent for three years, as against 29 per cent for five years treated by surgery.

(ii) Carcinoma of the alveolus treated by radiation has a survival rate after three years of 30 per cent, as against 33 per cent for five years treated by surgery.

(iii) Fauces tonsil and soft palate. Mr. Pitterson quotes forty cases proved by biopsy with a 22 per cent survival rate of five years, as against 20.8 per cent by radiation for three years.

(iv) In a previous report the Radium Commission quoted 25.7 per cent survival rate by irradiation for carcinoma of the tongue, presumably for three years, whereas surgery has given 25 per cent alive after five years.

(v) Irradiation of the cheek gave 37.4 per cent survival rate for three years, as against 70 per cent for five years in ten cases. Three have lived for over eleven years, one for eight and a half years. (Vide *British Journal of Surgery* October, 1937.)

(vi) As regards glandular involvement, there appear to be no statistics of the survival rate when irradiation alone was employed. Apparently 16.5 per cent were treated by block dissection and 56.5 per cent by radiation, but no recurrence-free rate for each group after three years is mentioned. Of twenty-three cases of proved glandular involvement in Mr. Pitterson's cases treated by block dissection alone, three patients were alive after 10 years 9 months, 8 years 10 months, and 7 years 11 months respectively. It often happens that glands diagnosed as malignant prove on section to be, so far as investigation is possible free from cancer cells. There is no proof, therefore, unless a section has been previously made, that a mass in the neck which was irradiated and which subsequently resolved was malignant, it may have been inflammatory.

(vii) Table 24. The net survival of all cases of carcinoma of the mouth treated by radiation is 16.6 per cent after five years showing a marked drop in proportion to the three years survival rate.

Quite a large percentage of post-operative deaths in Mr. Pitterson's series were due to bronchopneumonia. In more recent years, however, anaesthetics have improved so enormously as to render this complication much less common. The survival rate should therefore improve still further. Another factor standing out in the Radium Commission report is the fact that accurate classification and localization are extraordinarily difficult. As a rule, the surface extent of tumours, where surgery is not employed, is all that is known, the extent of penetration into the tissues and the relation of the mass to neighbouring structures are a matter for surmise. Where surgical removal is undertaken a much more accurate estimate is obtained of the magnitude of the tumour and its orientation.

It would appear that the best results in some cases will be obtained by a combination of surgery and irradiation. Surgery, however, in all but inoperable cases should be

considered the main weapon of attack. The pendulum has indeed swung too far in the direction of irradiation. One has only to read the original letters and obituary notice of the late Mr. Percy Furnivall (*British Medical Journal* May 14) to realize that actual irradiation is not the end of the story, and one is reminded again that severe pain is present in very many cases that survive radiation. It may be said of surgery that no new disease is introduced. Radium, however, may cause oedema, burns, necrosis of soft or bony structures, even osteomyelitis. These complications may necessitate the employment of surgical measures, sometimes of a serious nature, and too often unsuccessful—I am, etc.,

London, W 1, May 23 E. R. GARNETT PASSE, FRCS

### After-effects of Modern Treatment of Carcinoma

SIR—Mr. Percy Furnivall's distressing experience (*Journal* February 26, p. 450) was of great interest to those of us who practise radium therapy in India. In this district oral cancer is exceedingly common, upwards of 120 cases pass through this hospital annually. No doubt the responsibility rests with the native habits of betel chewing and tobacco smoking—the ladies here are partial to a cheap cigar smoked with the lighted end inside the mouth! So far as the limited supply allows, these cases are treated with radium, either embedded in the growth or in a mould, in the minority who consent to operation a block dissection of the neck is done later. Only a fraction of these cases are seen again. 'Follow up' in the sense that it is understood in Western clinics is unknown, the patients return to their villages for better or worse, and cannot be induced to report personally or to answer questionnaires. From the few cases which I have been able to follow I am beginning to doubt whether, despite the immediately favourable outcome, the end-results are equally satisfactory.

An Anglo Indian aged 44 was treated for an early epithelioma of the right side of the tongue, three quarters of an inch in diameter and of three months duration by a block (Crile) dissection of the neck on November 22, 1937 followed by the implantation of 11 milligrammes of radium on December 8 (1,900 milligramme hours in all). Owing to the radium not being immediately available, the usual procedure of 'tongue first' was reversed. The immediate result was striking: the ulcer melted away leaving a small slightly depressed scar. The patient returned to work early this year and all was well until early in March. Pain began again and though at first localized to the scar in the tongue and to the overlying skin was soon referred to the whole trigeminal distribution. His condition now is one of acute misery, work and sleep are impossible, as there is constant agonizing pain in the right side of the face and head, with periodic exacerbations resembling in their severity a true trigeminal neuralgia. There is no recurrence either locally or in the neck, but the pain has resisted anodyne drugs and injections of local anaesthetics for nearly three months.

Possibly, like Mr. Furnivall, he has had an overdose, or perhaps the "glands first" procedure may be blamed. How is one to estimate the dosage? Other very similar cases are seen in which, with the same dosage, we fail to destroy the growth, and regret that we had not given more. Without a 'follow-up' system we have not even our own experience to regulate dosage and having to rely on the published advice of others, our dosage is empirical. As Mr. Musgrave Woodman observes (*April 16, p. 870*) there is urgent need for team work between surgeon, pathologist, and expert physicist or radium officer, but in the absence of a statistical 'follow up' all are important. Our cases here are practically all

very advanced and this coupled with an almost child like faith in the efficacy of radium places a heavy responsibility on the surgeon. The problem of pain occurring after radium treatment is one which receives scant mention in standard works and in published series of cases I think a debt of gratitude is owing to the late Mr Furnivall for starting a discussion on a subject with which every surgeon must be unhappily acquainted—I am etc.

King George Hospital, Vellore, Madras, May 21

### The Active Principle of Cannabis Indica

SIR—It is a little surprising to read in the *Journal* of May 14 (p 1088) regarding *Cannabis indica* that the active principle has not been isolated. It was isolated, but perhaps not in its purest form over forty years ago in the Agricultural Chemistry Laboratory at Cambridge by Wood, Spivey, and Easterfield (*J. chem. Soc.* 1896 69 399). Many of its constants and much of its chemical constitution were determined. It is unstable being readily oxidized in air and can only be prepared by distillation *in vacuo* and kept in an atmosphere free from oxygen. Later these investigators obtained a higher homologue which was pharmacologically inactive, and to which they unfortunately transferred the name cannabinol. This mistake—for as such I regard it—has given rise to some confusion. The research was discontinued owing to Spivey being killed by an explosion during the continuance of the investigation. Sigmund Frankel (*Arch. exp. Path. Pharmacol.* 1903, 49 266) also isolated the active principle, cannabinol, and curiously enough he is credited in some textbooks with its discovery, but his investigations did not add materially to the facts determined at Cambridge. An account of the products chemistry and pharmacology with bibliography up to the time the article was written (1899) will be found in the *Textbook of Pharmacology and Therapeutics* edited by Dr (now Sir) William Hale White (Y. J. Pentland, Edinburgh and London 1901) pages 313-28—I am, etc.,

T. Cambridge Wells, May 20

C R MARSHALL

\*\* Since the pioneer discoveries of Wood Spivey and Easterfield much chemical work has been done on cannabis. The chemical structure of cannabinol was worked out by R S Cahn (*J. chem. Soc.* 1933, p 1400). The characteristic effects of cannabis are probably not due to cannabinol which is toxic but to some other substance. This view was supported by Cahn and has recently been confirmed by Bergel Todd and Work (*Chemistry and Industry* 1938 57 86). The really important active principle has not yet been isolated in the pure state.—Ed B.M.J.

### Placental Extract in Prevention of Measles

SIR—The following notes may be of interest, after Dr W E Crosbie's article on the prevention of measles in a children's hospital (*Journal* May 7, p 1003).

A measles epidemic occurred at St Hilda's Home for children of school age during October and November 1937. At the end of November a case occurred at The Elms, which is the home for children of 1 to 5 years. It was decided to immunize contacts in this toddlers home with placental extract. Twelve children were accordingly given an attenuated dose of 3 ccm. on the fourth day after the rash appeared in the original case. All the contacts except one subsequently developed measles, but in no case was the attack severe and complications did not occur. Five out of the eleven cases were appreciably developing a mild rash only on the trunk

and abdomen. There were no reactions following the injection of placental extract.

The interesting point compared with Dr Crosbie's findings is that although a smaller dose than his minimum was employed (3 ccm instead of 4 ccm) apparently better results were obtained. This might be due to the fact that the Alder Hey children were sick children whereas our group were healthy children and the former received their injection immediately measles was diagnosed in the ward whereas the latter were injected four days after the rash appeared in the original case. I am indebted to Dr P R McNaught (Medical Officer of Health) for permission to publish these results—I am etc.,

C B CRANE

Assistant Medical Officer of Health  
for York

York, May 21

### Tuberculin in Diagnosis

SIR—Dr R J Forbes (*Journal* May 21 p 1131) does not appreciate the fact that tuberculin tests are either generic or selective. All the skin tests are generic. A positive reaction means that the subject at some time or another has been infected by the tubercle bacillus and that his tissues have been damaged by the bacillus although the damage may be so slight as to escape detection on subsequent macroscopic or microscopical examination. With a positive generic test the infection may be either obsolete, latent and living harmlessly in the tissues as in a varying percentage of clinically non-tuberculous adults and children or active and causing tuberculous disease. A positive generic test by itself does not distinguish between these three possible relations of host and parasite. A selective test is one that distinguishes between obsolete and latent infection on the one hand and active disease on the other. By means of the subcutaneous test this may be done with a considerable degree of accuracy.

Tuberculin is the most exact and finest reagent for proving the existence of a tuberculous deposit in the living organism. The subcutaneous tuberculin test is the most practically serviceable and most fertile in results of the diagnostic methods. So wrote Bandelier and Roepke. In cases where the intracutaneous test has not been made or, if made, was positive to a dose of 0.00001 ccm of OT or T.A.F. I give the following subcutaneous injections (as explained in my *Tuberculin Handbook*) of T.A.F. with an interval of two days between each injection. Thus if the first injection was given on the first of the month the second would be given on the fourth.

A 1st injection of 0.000025 ccm (0.25 ccm D <sub>1</sub> ) and if there be no reaction a			
2nd	0.00005 ccm (0.5 ccm D <sub>1</sub> )		
3rd	0.0001 ccm (0.1 ccm D <sub>1</sub> )		
4th	0.0002 ccm (0.2 ccm D <sub>1</sub> )		
5th	0.0005 ccm (0.5 ccm D <sub>1</sub> )		
6th	0.001 ccm (0.1 ccm D <sub>1</sub> )		
7th	0.002 ccm (0.2 ccm D <sub>1</sub> )		
8th	0.005 ccm (0.5 ccm D <sub>1</sub> )		
9th	0.01 ccm (0.1 ccm D <sub>1</sub> )		

A febrile reaction to any dose of tuberculin up to 0.002 ccm (0.2 ccm D<sub>1</sub>) is proof of active disease. A negative reaction to 0.005 ccm or to 0.01 ccm excludes active tuberculosis. The smaller the provocative dose and the stronger the reaction the greater is the evidence of active disease. Conversely the larger the dose and the less the reaction the greater is the evidence against active disease. A positive reaction to 0.01 ccm may occur in clinically non-tuberculous subjects. I may illustrate this from personal experience. At the age of 26 on going to the Royal Victoria Hospital for Consumption my cutaneous reaction was negative. After six months I gave

a strong positive. In the interval I had been infected. Although infected I have never developed the disease. A year ago I again tested myself with the cutaneous test and was positive. I then tried the subcutaneous test, and gave no reaction until the test of 0.01 ccm was reached, when the temperature rose to 100° F. Yet the subcutaneous test is not a mechanical method of diagnosis, because with positive reactions to 0.005 ccm we are in no-man's land, where every other factor in the case must be given equal consideration. In the case of cattle, Kolmer analysed the results of 15,000 injections. A post-mortem examination of the animals showed that the error in the subcutaneous test was less than 3 per cent—I am, etc.,

London W 8 May 27

HALLIDAY SUTHERLAND

SIR—Dr J R Forbes (May 21, p 1131) asks for evidence of the value of the tuberculin reaction in the positive diagnosis and treatment of active tuberculosis. My reply is simple. Moreover, the evidence I supply is evidence of the value of tuberculin in diagnosis when all other evidence either fails or leads us astray—notably x-ray evidence and clinical examinations.

The special methods I advocate are the original methods of Robert Koch himself, implemented by those we owe to Ehrlich (1882), Arneth (1905), and later Schilling—by means of Koch's *subcutaneous* doses of tuberculin, first of all, followed in thirty-six or forty-eight hours by haematological analyses of the blood according to the methods of Arneth, or more easily and simply by Schilling's analysis of blood cells before and then forty-eight hours after the doses of tuberculin are given. If Dr Forbes is a well-trained haematologist and follows Arneth's method he will be able, with a microscope and an immersion lens, to observe under the conditions stated very definite changes in the granules and number of nuclei, and especially in the number of the neutrophil swag-like (*Stabkernigen*) cells in the neutrophil leucocytes of the blood, and also in the number of lymphocytes (I call these cells swag-like because in form and shape they remind me of the swag carried across his shoulders by the Australian "sundowner"). Two days after a proper dose of tuberculin the essential changes in the blood are an increase by 6 per cent of the (neutrophil *Stabkernigen*) cells and a diminution by 10 per cent of the lymphocytes. If the observations are continued for some months and longer with increasing doses of tuberculin the blood regains its normal character.

Facing page 420 in my work *Tuberculin in the Diagnosis and Treatment of Tuberculosis* Dr Forbes will find a fairly complete investigation of results obtained by Dr Guy Griffiths of Sydney and myself by means of Arneth's system of classification in 1905-8. These were my first investigations with Dr Griffiths's great help. I had sent for Arneth's book as soon as it was published, and the careful haematological examination of the blood for several years proved both to Dr Griffiths and myself the profound truth that treatment with tuberculin demonstrated beyond any doubt the specific effect of tuberculin after many months or years of treatment in restoring the blood to a practically normal condition. In fact I may say now that Case 40 (p 288) in my *Parkes Weber Prize Essay* was none other than Dr Guy Griffiths himself—a fairly striking illustration of the permanent value of tuberculin in treatment, as Dr Griffiths is alive to-day and carries on a crusade against tuberculosis in Sydney with wonderful faith in specific methods—I am, etc.,

W CAMAC WILKINSON M.D., F.R.C.P.

London W 1 May 23

SIR—Dr J R Forbes in his letter (*Journal* May 21, p 1131), tells us that he has read the recent correspondence on the above subject with some interest, and adds 'It would be instructive to learn what evidence Dr Camac Wilkinson and those who have written supporting him have of the value of the tuberculin reaction in the positive diagnosis of active tuberculosis.' In my letter (May 7, p 1026) I offered to send to anyone sufficiently interested to write for it a reprint of a paper in which some such evidence is offered. I have a list of those who have availed themselves of this offer, but I do not find Dr Forbes's name on the list—perhaps because he did not know my postal address.

Dr Forbes then puts forward a hypothesis of his own imagination 'if active tuberculosis be diagnosed on the sole finding of a positive tuberculin test.' This is never done by me. The patients to whom I apply the *subcutaneous tuberculin test* are those who have symptoms and/or signs strongly suggestive of tuberculosis, but not absolutely conclusive—for example, patients with pleurisy with or without effusion, but with no sputum or with no tubercle bacilli in the sputum. Some, to be on the safe side, would treat all these cases as tuberculous, but the subcutaneous tuberculin test has enabled me to eliminate about 40 per cent of doubtful cases as non-tuberculous, thus achieving the opposite to what Dr Forbes has supposed. In the case of those who react to the subcutaneous test my figures show that it is desirable for them to have treatment for tuberculosis at this stage instead of waiting till unmistakable signs and symptoms develop, when it may be too late—I am, etc.,

28 Knockdene Park South,  
Belfast May 23

JOHN R GILLESPIE

SIR—Assuming that a diagnostic tuberculin test is positive (see my letters in the *Journal* of January 15 at p 145, and in *The Medical Officer* of February 12, at p 72), it does not necessarily follow, as Dr J R Forbes suggests (*Journal*, May 21, p 1131), that "many healthy people may be subjected to unnecessary mental distress by being stigmatized as tuberculous." Such cases would not be notified and would not leave their work unless, after a few months' treatment with tuberculin, the disease was not controlled (as shown by the temperature chart and weight) and the condition indicated the need for a period of rest. It is impossible for those who believe that the earliest diagnosis of pulmonary disease can be made with tuberculin to bring forward convincing evidence that such diagnosis is reliable. These cases are negative to x-ray, clinical, and sputum examinations, and most workers demand that one or more of these investigations are positive before accepting a diagnosis of active disease. Tuberculin injections should be supported by a history taken with meticulous care, a four hourly chart of the temperature and pulse rate, and a differential blood count. It is, however, an unfortunate fact that if a diagnosis in pulmonary cases is based on the above methods, and is followed by successful treatment with tuberculin, after recovery the patient is apt to believe he was never infected. Friends are usually very assiduous in encouraging such a belief because the patient will never have appeared ill to them, especially so if he has not relinquished his work. This explains why careful discrimination is necessary in selecting the patients to whom the diagnosis may be made known.

Whether the claims for tuberculin can be established or not, no one can deny that in phthisis there must be a stage of the disease when the changes are cellular only and unrecognizable by ordinary methods of examination,

this is the stage at which tuberculin is supposed to react with the damaged tissue cells. I have many charts showing typical temperature reactions after injections with tuberculin given to non-pulmonary cases of tuberculous infection—I am etc.,

West Wickham, Kent May 23 H S BURNELL JONES

### Matrimonial Causes Act

SIR,—The letter by Sir Robert Armstrong Jones published in your columns last week is interesting, in that it shows the doubts that must necessarily be exercising the minds of those who may be called upon to give opinions for the purposes of the Matrimonial Causes Act. I feel therefore, that it may be of interest and possibly also of assistance to your readers to know of the advice which the Council of this Society has decided after mature deliberation to give to its members.

The Council realizes that the Law has certain faults and fallacies indeed, what Law has not but at the same time it takes the view which Sir Travers Humphreys so ably expressed—namely, that the courts and not the medical practitioners will decide these cases. In the circumstances, if the practitioner feels that he can say that a patient is incurably of unsound mind or likely to remain of unsound mind, he should when requested, give such information to the responsible relative. The Council considers that the ordinary relationship of doctor and patient does not exist in these cases for the patient does not voluntarily consult the doctor in whose charge he is, seldom has any voice in choosing that doctor and can, without his consent be removed from one institution to another. The question of breach of the patient's privilege of professional secrecy does not therefore arise, and the only question with which the doctor is concerned is that of prognosis.

As regards the possibility of an action by a former patient against the practitioner who has given his opinion in such a case it must be remembered as has been pointed out above, that these cases will be decided by the court and not by the doctors. The court will of course be influenced by the doctor's evidence but will not be bound by it any more than it is bound by experts in other cases. In these circumstances it would seem extremely improbable that any action can be brought against a doctor, for it would first seem necessary to upset the court's decision.

The patient's interests will be looked after in every case by the official solicitor, if not by a solicitor privately instructed and it is therefore perfectly safe to say that the patient's interests will be fully represented when the divorce proceedings are heard—I am, etc.

RICHARD W DURAND

Secretary London & Counties Medical  
Protection Society Ltd

May 20

\*An article on this subject appears in our Medical-Legal column this week—Ed B.M.J.

### Mechanical Diagnosis

SIR,—I was much interested in the summary of Professor F S Langmead's address on Retrospect and Prospect in Medicine (*Journal* May 21 p 1122). This experienced medical teacher expresses views of a kind to which I myself drew attention a short while ago—namely that the reliance largely upon instruments of precision as a means towards diagnosis is to a considerable extent discouraging the faculty of learning through the use of the eyes, the fingers and the ears. In my presidential address to the Metropolitan Counties Branch in June, 1946 on Observation, I used the following words

The tendency of late years to make use of many complicated instruments as aids to diagnosis has I think had in some instances an unfortunate result. So called instruments of precision are not always infallible any more than we or our lives are but the growing tendency of the day—to rely largely upon mechanical means of diagnosis—is to my mind rather overdone. It has often appeared to me that some of the younger generation are almost afraid of their own opinion and always seem to require other help. Is it that they know too much or has the training of their five senses been retarded and overshadowed by undue reliance upon instrumental aid?

I am glad to see that so experienced an authority upon the teaching of medicine as Professor Langmead is also doubtful of the wisdom of allowing the cultivation of our five senses to fall into desuetude in any way. Their proper uses under correct training, are of far more service than some of the mechanical adventitious aids which nowadays clutter up the modern consulting room, and their cultivation encourages that valuable asset—self reliance—I am etc.,

London W1 May 24

PERCY B SPURGIN

### The Psychology of the Medical Profession

SIR—Is it not time that some investigation was being made into the psychology of our profession? I am prompted to make this suggestion for several reasons but particularly from observing the constantly augmented flow of circulars about proprietary medicines—stimulants, sedatives, anti-spasmodics, vitamins, hormones, and all the rest of them—which are now arriving by every post. I can hardly imagine that this is some stunt of the Post Office to increase its revenues. It is apparently the firms themselves who do this and for the simple reason that it pays. They seem to be animated by an underlying conviction that the average member of our profession either has not the time or is no longer capable of thinking for himself, but is on the other hand eminently susceptible of suggestion and therefore makes an ideal unpaid agent for popularizing the said drugs among the general public. These enterprising firms must be doing well. Their folders show that they do not hesitate to take the whole field of medicine for their province and they are always only too ready to pour out the wealth of their learning for the benefit of the young, the inexperienced, and the too often baffled disciple of Hippocrates.

I am serious Mr Editor. It nothing is to be done about this, why not scrap the medical curriculum and let members of the coming National Health Service be educated as they go along by correspondence classes arranged under the auspices of the Drug Manufacturers' Union? Just think of the saving in time and expense! The universities and medical schools might not like the innovation but what would that matter when as we know, human lives are at stake?—I am etc.

North Queensferry Fife May 29

A. J BROCK

### "Cyclopropane Erythema"

SIR—I should like to report two cases of a peculiar erythematous rash occurring soon after the induction of anaesthesia with cyclopropane. Both cases were in young women aged 21 and 24 respectively. The rash appeared first on the neck then on the chest and abdomen and lasted for about fifteen minutes. It was similar to the more familiar ether erythema. No history of a previous skin disorder could be obtained in either case, and the rash was not present before induction with

cyclopropane For premedication each patient was given omnopon grain 1/3 and scopolamine grain 1/150 three quarters of an hour before operation I should be interested to hear of further cases of this condition—I am, etc,

VICTOR J KLATING,

London W 12 May 25 Resident Anaesthetist British Postgraduate Medical School

### Divinyl Ether Anaesthesia

SIR—I have read with great interest Dr C F Hildfield's letter on the subject of divinyl ether (*Journal*, May 28, p 1175), and although I have never used it in a Clover's inhaler I have on many occasions administered it in a closed circuit, using Waters's canister and a Boyle's apparatus The resulting anaesthesia has been satisfactory in every way but I have recently had two cases which developed convulsions indistinguishable from those occurring under ethyl ether anaesthesia The head of the operating table was raised as far as possible and 2 ccm of evipan given intravenously The convulsions ceased immediately and recovery was uneventful The rectal temperature was taken, but was not raised above 100° F in either case

In view of the possible occurrence of these convulsions I consider that divinyl ether should be used with caution in those cases where full surgical relaxation is required—I am, etc,

London, NW 3 May 27

C J M DAWKINS

### Unusual Reactions to Procaine

SIR—I feel that the following experience should be placed on record as likely to be of interest to physicians accustomed to using procaine as a local anaesthetic

I was recently engaged in giving a series of artificial pneumothorax refills to cases of pulmonary tuberculosis My technique was, as usual, to give a preliminary local anaesthetic by infiltrating the skin and pleura—with about 1 ccm of 2 per cent procaine prepared by a leading firm of chemists I performed the operation on patients A and B without apparent untoward effect, and proceeded with patient C During the course of this refill the patient complained of a feeling of drowsiness, but his appearance was normal and so I proceeded to complete the operation A few moments later the nurse called me, and I found the patient lying unconscious His breathing was heavy, but his colour was good and his pulse steady his pupils were moderately contracted His whole appearance was that of a person under deep narcosis, although at the time I was at a loss to explain his condition While attending to this patient I was interrupted by a call to patients A and B Both were complaining of dizziness drowsiness and inability to keep the limbs still although fully conscious Patient C, meantime was slowly recovering He complained of his head going round and round and of difficulty in keeping his limbs still All three patients were completely recovered in about an hour and were able to return home For three further refills that afternoon I used separate ampoules of procaine without ill effect

It appeared to me as probable that the patients were suffering from procaine poisoning Against this was the fact that the solution used was from the last ounce of a four ounce bottle which I had been using regularly for several weeks On further inquiry I ascertained that on the two preceding weeks at least four patients (including patient B) had felt extremely drowsy, and one had slept soundly for an hour None of the patients, however had thought it necessary to trouble me with any complaint It seemed that the solution had undergone some progressive deterioration probably patient C was more susceptible than the others and his extreme symptoms brought the matter forcibly to my notice The remains of the solution were returned to the makers who

report is follows 'Our research laboratory have examined the procaine solution returned and report a concentration of 1.54 per cent procaine hydrochloride This low result is difficult to understand and suggests unexpected deterioration The matter in view of the reactions, is very important and it is unfortunate that more of the solution was not available for further investigation

It would be interesting to hear of any similar experiences and of any suggested explanations The solution in question had been in stock for about three months, and in obvious conclusion would seem that it is inadvisable to keep stock for so long a period I must add, however that I have used procaine solution constantly for fourteen years and have never previously had any unpleasant reactions, although I feel sure that the solutions used have sometimes been more than three months old—I am, etc,

T W PRESTON, M D, M R C P

London W 1, May 28

### Aperients and Sulphanilamide

SIR—My colleague, Dr J L W Ball, was recently called in to a case of puerperal pyrexia, and was prevented from administering sulphanilamide by reason of the midwife's having given the patient an aperient of Epsom salts This and the sulphur containing compound liquorice powder are favourite aperients among midwives, and he is of opinion that a general warning ought to be issued to them to avoid the use of these substances altogether While most puerperiums go on naturally it is impossible to say beforehand that any given case will not require sulphanilamide, and there is no reason why the 'pitch should be quered' by the previous administration of sulphur or its compounds when so many other good aperients are available I agree with him that the point is important enough to be taken seriously by medical officers of health and others who have to do with the control or education of midwives As a side issue it would be interesting to know, if quinine is given, whether the small amount of sulphur contained in the sulphate is sufficient to cause trouble with sulphanilamide If so, it should be the routine practice to order the hydrochloride or the hydrobromide—I am, etc,

Lough May 24

JOSEPH JONES, M D

### Atrophic Rhinitis

SIR—In his excellent article on nasal conditions in the *Journal* of May 28 (p 1167) Mr E D D Davis refers to atrophic rhinitis This disease is almost always the result of an undiagnosed sinusitis in children, which is now, but only now, beginning to receive proper attention The late J S Fraser came to share this view with me, and the truth of it I have proved by the results of treatment The essential treatment is that of the sinusitis Intranasal surgery usually suffices The ethmoid in practically all cases is involved and is the key to the problem, but the sphenoids and intra also often need attention Once the sinusitis is cured, crusting and foetor promptly lessen and often cease The atrophy, of course, remains, but the mucosa improves, especially if the nostrils can be narrowed by implants The disease has therefore no essential connexion with tuberculosis, though it may predispose to it and to bronchiectasis

Another point of practical importance is that most of these atrophic cases harbour diphtheroids, and if swabbed, unless the virulence test be done, will be reported as cases of diphtheria and uselessly isolated at great and unnecessary cost to the community, as Dr John Reid has pointed

out In two cases where this happened the bacillus was a missed foreign body which had set up sinusitis and atrophy both cleared up on removal of the foreign body—I am etc

Glasgow May 28

JAMES ADAM

### Treatment of Placenta Praevia

SIR—In *A Handbook of Midwifery* which I used as a student about thirty seven years ago W R Dakin advised that the placenta should be separated over its large area as possible by introducing the finger as far as the second joint and sweeping it round under the placenta in a circle. Since then I have assisted at or performed the necessary manipulations on the abnormal cases occurring among about 5,000 confinements including over 500 hospital district cases. I may have been exceptionally fortunate but I have never seen this simple procedure fail to stop the haemorrhage. I give this as a personal experience but as I have done little midwifery in the last twenty years I will leave discussion as to what should be done after the haemorrhage has ceased to the writers of the interesting letters recently published—I am etc

Altrincham May 24

ARTHUR T BLEASE

### Sterilization of Syringes

SIR—In all the correspondence on the sterilization of syringes I have looked in vain for the enunciation of what is to my mind the most essential point of all—namely the thorough cleansing of the needle and syringe immediately after use. If this is done the efficient sterilization of the instruments is a comparatively simple matter. The needle and syringe should be thoroughly washed through with ordinary tap water to remove all visible foreign matter and then completely immersed in the selected sterilizing medium, care being taken to see that the lumen of the needle and of the syringe is filled with the sterilizing fluid and that there are no bubbles. Personally I have used industrial spirit as a sterilizing medium for many years with satisfactory results.

The needle and syringe are placed on one side to be washed and sterilized at some later and more convenient opportunity blood adheres firmly to the inside forming a protecting layer round any germs that may be caught in the clot. The efficient cleansing and sterilization of such a needle and syringe can never be guaranteed. Should the needle be used in any case where infection is suspected it must not be used again on another case. It is of course, essential that needles and syringes should be free of all grease or other foreign matter that might protect germs.

Cleanliness is indeed next to godliness. A dirty syringe cannot be made sterile—I am etc,

London May 30

ST GEORGE B DELISLE GRAY

### "Spontaneous Combustion"

SIR—Your note in the *Journal* of May 21 (p 1106) on spontaneous human combustion is very interesting. It is surprising how common was the belief in its occurrence some hundred years ago. Plouquet in his *Literatura Medica* related twenty eight cases and Dr Trotter in an essay on drunkenness quotes many others. A paper entitled *Essai sur les combustions humaines produites par l'abus des liq spirit.*, written in Paris in 1808 by Pierre Lair was devoted entirely to this subject.

Dr Paris to whom you refer in your note lays it down in his *Medical Jurisprudence* published in 1823 that the recorded cases have these things in common (1) the victims are chronic alcoholics (2) usually elderly females (3) the body has not burned spontaneously but some lighted substance has come into contact with it (4) the hands and feet usually escape (5) the fire has caused very little damage to combustible things in contact with the body (6) the combustion of the body has left a residue of greasy and fetid ashes very offensive in odour. In this work there is a full account of the case of the priest Bertholi—I am etc

## Medico-Legal

### DIVORCE FOR INSANITY

The courts are now beginning to grapple with some of the problems set them by the provision in Herbert's Act—the Matrimonial Causes Act 1937—which makes confinement for five years because of incurable insanity a ground for divorce. One of the chief of the new difficulties is to prove that the condition is incurable. As all psychiatrists know some patients recover after five years and a few after twenty five so there is no absolute rule by which incurability or irrecoverability, can be predicted. The courts however will probably continue to follow the common sense lines which they have always pursued in dealing with matters of fact: they hear the best evidence and give their decision on what they consider to be a reasonable probability.

The evidence must be the best and the President commented in one case heard on May 24, on the calling of a medical superintendent who had only been in the hospital for a few weeks when the petitioner might have called a medical officer who had been there for twenty years. He said that he wished it to be clearly understood that the court would expect the best possible evidence with regard to a respondent's mental condition from the place where the respondent was detained. Possibly a large number of respondents will be found to be suffering from secondary dementia of which the chance of cure is practically nil. As Sir Travers Humphreys remarked the other day from the chair at a meeting of the Medico-Legal Society, before which Mr William Lacey read an instructive paper on this subject the court will ask whether the respondent is curable from the point of view of marriage. It is not likely that the possibility of a mere remission of the symptoms of dementia leaving the respondent in a rational but feeble and relatively incapable condition of mind would count as curability.

None of the cases that have been heard hitherto has elucidated any of the substantial legal difficulties many of which were enumerated by Sir Robert Armstrong Jones in the *British Medical Journal* of May 28 (p 1177). The question of whether a doctor who gives evidence about a patient's condition for the purposes of a petition against the patient is liable to unpleasant legal consequences has not so far been approached. The Act provides no penalty for a medical officer who refuses information and thereby in Sir Robert's phrase stultifies the law and he would not be liable to one unless he were to refuse a direction in the subpoena to attend court and give evidence and perhaps to bring the case records with him. A doctor may well raise every objection to giving information about the state of a private patient, but most of these inquiries are likely to be made of mental hospital superintendents. As the patients to whom the inquiries relate will almost certainly be certified it can hardly be said that the confidential relation between doctor and

patient exists in such a form as to prevent an officer, charged by law with the detention and care of the patient, from giving information for the purposes of assisting the administration of justice. The best way of bringing the information before the court would probably be through some impartial channel rather than through the petitioner's solicitors. Mr Latey made in his paper and in his handbook on the Act,<sup>1</sup> the valuable suggestion that the court itself should appoint medical inspectors, who would inquire into a respondent's mental state just as at present a panel of inspectors inquires into the condition of parties to a nullity suit. The Royal Medico-Psychological Association considers that superintendents should offer to supply information to the patient's guardian *ad litem*. In *Timms v Timms*, heard before the President on May 24 the Official Solicitor made an independent inquiry into the medical history of the case and the prospects of recovery. The result of that inquiry was that the evidence in support of the petition remained unchallenged and was conclusive. In this case the Official Solicitor was the guardian *ad litem* appointed by the court; this appointment is often made when the court considers it desirable. This particular question will solve itself, on the basis that it is the duty of a doctor to assist in the administration of justice. As Dr R D Gillespie pointed out in discussing Mr Latey's paper doctors already, in certifying patients often have to see the patient without letting him know the object of their visits and they must divulge the facts which they learn directly and from others. This duty is not very different from their function as witnesses in a divorce action. Some writers, Sir Robert among them, have suggested that a doctor who gives evidence that a patient is incurable may be liable to have an action for negligence brought against him if the patient should afterwards recover. This fear is quite groundless for the reason that no action of law can lie in respect of evidence given in judicial proceedings. It is absolutely privileged, so that witnesses may be encouraged to tell the truth without fear of consequences. As any opinion given by a doctor would be given for the purpose of judicial proceedings and in good faith, he would be protected.

### PAYING PATIENTS AT BART'S

Voluntary hospitals, in their efforts to pay their way, are now all obliged to take paying patients. Even in this activity they are forced to compete with the municipal hospitals which are springing up under the Local Government Act, 1929, and which are not handicapped by the terms of trust deeds. The Voluntary Hospitals (Paying Patients) Act, 1936, allows the Charity Commissioners to make an order permitting a voluntary hospital to provide accommodation for paying patients, but the commissioners cannot authorize any breach of trust. A voluntary hospital can, therefore only provide for paying patients if it is making proper provision for the sick poor as required by its trust deed. In 1935 St Bartholomew's Hospital asked Parliament for power to provide a paying patients department at the expense of a fund specially raised for the purpose. Unfortunately, instead of getting the required £124,000 the hospital was only able to raise £10,000. It was therefore obliged to promote a Bill to secure power to use the general funds of the hospital for the provision of a paying patients' department. The Bill was introduced in the House of Lords, and, although no petitions were lodged against it, the Chairman of Committees decided that, in view of its importance, it should be treated as an opposed Bill and sent to a Select Committee.

On May 24 the committee rejected the Bill. Sir Claud Schuster K.C., permanent secretary to the Lord

Chancellor, said in a preliminary statement that the Lord Chancellor, although he did not oppose the Bill, drew the attention of the committee to the great inroad on the law of trusts which the Bill proposed. The funds of the hospital were vested in a charitable trust for the benefit of the sick poor and the Bill proposed to apply them to some other—no doubt deserving—purpose. Sir Lynden Micassey, K.C., who appeared for the hospital, said that the Bill was essential to preserve its efficiency. Every teaching hospital in London except St Bartholomew's and Charing Cross had paying patients departments which enabled the medical and surgical staff to supplement their honoraria by fees from paying patients. At Bart's the staff received only 50 guineas a year and the real fear of the Governors was that young and promising surgeons and physicians would be deterred from taking appointments there. Mr George Aylwyn, treasurer of the hospital, said that in his view the term 'sick poor' should be enlarged to include people with £500 to £1,000 a year but the chairman of the committee, Lord Redesdale, replied he could not think that 'sick poor' ever possibly meant people with £500 or £1,000 a year. Mr Andrews Uthwatt, on behalf of the Attorney-General, the constitutional guardian of charitable trusts, said that the only chance of the funds coming back and being applied to their original purpose would depend on the success of a commercial venture. The committee therefore rejected the Bill, and the last state of Bart's is worse than the first, for private Bills are expensive things. The incident points clearly to the need for some constructive scheme that will put the whole voluntary hospital system on a practical basis.

## Obituary

### DAVID PETER GAUSSEN, M.D.

The death of Dr D P Gausson of Stewartstown, Co Tyrone,<sup>1</sup> has removed one of the older practitioners who did so much to establish themselves in the affections of the people. Dr Gausson was a student of the old Queen's College of Belfast and graduated M.D. of the Royal University of Ireland in 1883. He had studied also at St Thomas's, obtaining the M.R.C.S. in the same year. He was a widely read gentleman, an experienced practitioner, and beloved by all who were fortunate in his acquaintance. For very many years he practised in Dunmurry, a few miles out of Belfast. He was well known and much respected by his colleagues in the city, and always interested in affairs pertaining to the welfare of the profession. He was elected a member of the British Medical Association in 1884, and was chairman of the Belfast Division in 1906 and president of the Ulster Branch in 1925-6. He had also been president of the Ulster Medical Society. He filled these positions with dignity and distinction. Some years ago he retired from active practice and lived in County Tyrone, where he enjoyed several years of respite. Withal his interest in medical affairs was maintained. He frequently attended meetings in Belfast. He was interested in the 1937 Annual Meeting of the British Medical Association, having attended the previous two meetings there, extending over a period of fifty-four years in all. With his widow and daughter there is widespread sympathy in their loss.

Dr S R Hunter writes: As one who worked in friendly rivalry with the late David Peter Gausson for over twenty years I should like to express my appreciation of his worth as a medical practitioner and to bear witness to

<sup>1</sup> 1937 Sweet and Maxwell

<sup>2</sup> *Times* May 25, 1938

the great esteem and respect in which he was held not only by his patients and friends but also by his medical colleagues in the North of Ireland. A descendant of the Huguenots who settled in the district in the seventeenth century he qualified in time to attend the Annual Meeting of the Association held in Belfast for the first time in 1884, and thus had the unique experience of attending all three Annual Meetings of the Association in Belfast. He was elected president of the Ulster Medical Society in 1906 and had a rather disturbing experience at the opening meeting. Arriving at the Whitla Medical Institute to deliver his presidential address he discovered he had mislaid his copy of the manuscript. Such was the quality and character of the man, however, that he delivered an excellent discourse from a few rough notes from which his address had been prepared. He was a careful and skilful obstetrician and contributed several papers to the journals on this subject. Although over the age limit he served in the R.A.M.C. in the hospital ship *Britannic* acting as adjutant to the medical officer in charge—an old Dunmurry patient and friend. He had many interests outside his professional work: he was always a good sportsman and a keen supporter of athletics. He had during the course of his long life been president of football and cricket clubs, a past captain and honorary member of the Dunmurry Golf Club and in his earlier years had acted as conductor of the local musical society. He was also a firm supporter of the Masonic order in which he reached high office and distinction. Owing to the state of his health he retired from active practice in 1927 leaving Dunmurry to reside in Stewartstown. His friends and patients took this opportunity of presenting him with an address and substantial cheque as a token of their respect, admiration and affection.

#### LAWRENCE ALFRED JOHNSON M.R.C.S.,

Honorary Secretary YORK DIVISION B.M.A.

The York Division of the British Medical Association has sustained a sad loss in the unexpected death on May 21 after a slight operation of their energetic and genial secretary Dr L. A. Johnson, at the age of 68. He leaves a gap which it will be difficult to fill.

Receiving his medical education at Leeds Dr Johnson qualified M.R.C.S., L.R.C.P. in 1892, and began his medical career at Normanton where he was medical officer of health for many years before going in 1921 to Telford where he practised for thirteen years. Retiring from active practice in 1934 he went to live at Copmanthorpe near York. He took an active part in local affairs: he was chairman of the Parish Council and represented the township on the Appleton Roebuck and Copmanthorpe District Drainage Board and was always ready to place his services at the disposal of local practitioners needing help in emergency—services which were much in demand and very highly appreciated for he was a country practitioner of the best type with wide experience and yet up to date in his medical knowledge. But his principal activities since his retirement were in connexion with the York Division. For several years the Division had been in considerable difficulties in regard to the secretaryship, a post which the younger men did not seem able or willing to fill. Dr Johnson always an active and useful member on his retirement although past middle age (he was then 65) stepped into the breach and putting into it all the vigour of his energetic nature rapidly united the Division together again. He was untiring in his zeal for the profession and nothing was too much

trouble for him. He was responsible for the success of the annual meeting of the Yorkshire Branch in York in 1931 and for well attended anti gas lectures held last year. A man of most genial and likeable temperament he was *persona grata* with all the members who will personally mourn his death while the Division as a whole will deplore his unexpected loss at a time when it appeared likely that Division affairs would remain in the same good hands for years to come.

J. C. LYTH

News has been received in this country of the death in Northern Shansi of Dr HENRY GEORGE WYATT of the Baptist Mission Hospital Taiyuan North China, to which he was attached as medical officer. According to the *Times* Peking correspondent, Dr Wyatt with two ladies and an Englishman and a Chinese chauffeur left Taiyuan in a motor car and after travelling eighty miles were fired upon in error by a mobile Chinese unit. Dr Wyatt behaved with the utmost bravery in endeavours to save his companions and died in a roadside ditch to which he had carried the unconscious chauffeur on his shoulder in a fusillade. He had studied medicine at the London Hospital taking the English Conjoint diplomas in 1924, the M.B. B.S. Lond. in the same year and the F.R.C.S. Ed. in 1931. He contributed several papers to the *Chinese Medical Journal* and had been a member of the Hong Kong Branch of the British Medical Association for the past ten years.

An obituary notice of the late Lieutenant Colonel EDWARD WILKINSON appeared in the *Journal* of May 14 (p. 1077). Lieutenant-Colonel Henry Smith C.I.E., I.M.S. (ret.) sends the following tribute. I have known intimately Colonel Wilkinson from almost the beginning of his service in the I.M.S. till his end, as a personal friend whose death I lament. He was a man capable of constant and reliable friendship which no passing event would cause to waver. He was a man of fearless honesty and indomitable moral courage and as such was not by nature adapted to the career of a courtier but to that of a man who depended on his personal worth alone. Like all those who knew him I lament the loss of such a friend.

Dr THOMAS CHETWOOD chief school medical officer for the City of Sheffield died suddenly on May 11 at his home in Grange Crescent aged 63. From Epsom College he entered the London Hospital and took the English Conjoint qualification in 1900 the M.B. Lond. in 1903 and the Oxford D.P.H. in 1910. He had been house physician senior clinical assistant casualty officer and resident anaesthetist at the London Hospital and district surgeon at the City of London Living in Hospital. Dr Chetwood went to Sheffield in 1914 and joined the Sheffield Health Department there: he wrote the annual reports of the Sheffield School Medical Service from 1914 to 1934 and for some years was lecturer on hygiene in the University. He became a member of the Sheffield Division of the B.M.A. in 1921.

The death is announced in Sweden at the age of 76 of Professor J. E. JOHANSSON the physiologist. His duties as professor of physiology at the Karolinska Institute in Stockholm and as a member of the Nobel Committee between 1904 and 1926 did not prevent him from taking an active part in social problems with a medical aspect. One of his most important publications dealt with the frequency of pulmonary tuberculosis in different parts of Stockholm in relation to density of population and economic status. He played a prominent part in the abolition or regulation of prostitution in Sweden whose new legislation with regard to the venereal diseases was considerably influenced by him.

Dr THOMAS LONGMORE ASHFORTH died on May 27 at his home in Woodlands near Doncaster. After qualifying in medicine at the University of Glasgow he took the Scottish triple qualification in 1902. He was the first medical practitioner at the Woodlands colliery village, which was built for the workmen at Brodsworth Main Colliery some thirty years ago. He took the DPH of Sheffield University in 1922 and had been assistant M.O.H. for Hamilton and visiting physician to the Hamilton Fever Hospital. During the war he served as captain R.A.M.C. with the 66th and 33rd Divisions and was adjutant to No. 40 Stationary Hospital at Havic. For many years Dr Ashforth was lecturer for the West Riding under the Central Midwives Board, and corps surgeon for the colliery ambulance brigade.

Dr ARTHUR TANNER COOPER died of pneumonia on May 24 at his home in Leicester where he had practised for the last twenty years. Born at Heston Middlesex, on May 23, 1869 he was educated privately and at University College, London, qualifying M.R.C.S. L.R.C.P. in 1892. He then served as house-physician to the National Hospital for Diseases of the Heart, house surgeon to the Hospital for Women in Soho Square and to the Royal National Orthopaedic Hospital, and during the war he held a temporary commission as captain R.A.M.C. Dr Cooper joined the British Medical Association in 1909, and since the war had been a member of the Leicester and Rutland Division.

The following well-known foreign medical men have recently died. Dr GEORGE MARINESCO professor of clinical neurology in the Bucarest faculty of medicine, member of the Bucarest Academy of Medicine corresponding foreign member of the Academie de Medecine, and honorary foreign fellow of the Royal Society of Medicine, Lieutenant-Colonel JULIEN RABAUT director of the services of hygiene in the French concession at Shanghai. Dr LORENZO BARO formerly physician to King Alphonso XIII of Spain, Dr ALFRED HERMSTEIN extraordinary professor of gynaecology at Breslau, aged 46. Dr PAUL PETZOLDT a Dresden hygienist, aged 79, Dr JOHANNES JOHANNSSON formerly professor of physiology at Stockholm University, president of the permanent committee of international physiology congresses, and for many years president of the medical section of the Nobel Prize awards, Professor GUSTAV BAYER head of the institute of experimental pathology at Innsbruck. Dr BROR GADELIUS professor of psychiatry at the Carolinska Institute of Stockholm, aged 43, Dr ALFRED ZUBER a prominent Paris paediatrist, aged 73, and Dr ALFONSO DI VESTEA emeritus professor of hygiene at Pisa, aged 83.

## The Services

### INDIAN MEDICAL SERVICE DINNER

The annual dinner of the Indian Medical Service will be held at the Trocadero Restaurant London on Tuesday June 14, at 7.15 p.m. when Major General E. W. C. Bradfield C.I.E., O.B.E. the Director General, I.M.S., will preside. Tickets may be obtained from the honorary secretary, Major Sir Thomas Carey Evans, Hammersmith Hospital, Ducane Road, W.12. The Secretary of State for India, the Marquess of Zetland G.C.S.I. G.C.I.E. will be present as a guest.

### HONORARY PHYSICIAN TO THE KING

Surgeon Rear Admiral L. Warren O.B.E. R.N. has been appointed Honorary Physician to the King.

### DEATHS IN THE SERVICES

Colonel VIVIAN BOASE BENNETT Bombay Medical Service (ret.) died at Castletown Isle of Man on May 21 aged 71. He was born on April 20, 1867, the son of the late Rev

Matthias John Boase Bennett of Leeds and was educated at Liverpool and St. Bartholomew's Hospital. He graduated M.B. Lond. in 1891 and B.S. in 1893 and became an F.R.C.S. in 1906. He entered the Indian Medical Service as surgeon lieutenant on July 28, 1894, attained the rank of colonel on October 20, 1921, and retired on April 20, 1924. His first ten years' service were spent in military employ during which he served on the North West Frontier of India in the Tirah campaign of 1897-8 receiving the medal with two clasps. In April 1905 he was appointed a civil surgeon in the Bombay Presidency, in February 1909 he was posted as civil surgeon and superintendent of the medical school and lunatic asylum at Huddersfield, Sind, and in 1910-11 he served as senior surgeon of the Jamsetji Tijiabhai Hospital Bombay, and professor of surgery in the Grant Medical College Bombay. During the war he was recalled to military duty from 1916 to 1919. In May 1919 he was appointed civil surgeon of Poona and on promotion to administrative rank in October 1921, became A.D.M.S. at Poona and held that post until he retired. He had been a member of the British Medical Association since 1898.

Lieutenant Colonel VIVIAN HEATHCOTE ROBERTS I.M.S. (ret.) died in St. Mary's Hospital on May 22 aged 63. He was born on July 20, 1874 and was educated at the Grant Medical College Bombay where he obtained the diploma of L.M.S. in 1896. After filling the posts of Mayo demonstrator and tutor in physiology and histology at the Grant Medical College he went to Europe and took the Scottish triple qualification in 1898 and subsequently obtained the F.R.C.S. Ed. in 1909. He entered the Indian Medical Service as lieutenant on January 28, 1899, became lieutenant colonel on July 28, 1918 and retired on July 20, 1929. He served in the China War of 1900 (medal) in the war of 1914-18 when he was in Iraq from September 1914 to December 1916 and in Afghanistan in 1919. He had been a member of the British Medical Association since 1905.

Lieutenant Colonel CHARLES DUER Bengal Medical Service (ret.) died on November 20, 1937 aged 73. He was born on December 10, 1864 the son of Mr S. Duer a civil engineer of London and was educated at University College, London. He took the M.R.C.S. L.R.C.P. in 1888 the M.B. Lond. in 1889 and the F.R.C.S. in 1891. He entered the Indian Medical Service as surgeon on July 28, 1891, became lieutenant colonel after twenty years' service and retired on November 29, 1913. After four years' military service he was posted to civil employ in Burma in February, 1896, at first as resident medical officer of the Rangoon General Hospital then as junior civil surgeon, Rangoon in March 1899 and as senior civil surgeon Rangoon, in November, 1907. In August 1910 he was transferred to the Punjab as civil surgeon of Simla. After retirement he rejoined for service in the war of 1914-18, on October 19, 1914, and served to May 13, 1919, at first in the York Place Hospital for Indian Troops at Brighton till the end of 1915 and subsequently at Malta. He had been a member of the British Medical Association for thirty three years and in 1905-6 was a member of the Central Council of the Association.

Lieutenant Colonel HERBERT JAMES WALTON Bengal Medical Service (ret.) died at Godalming on May 4, aged 69. He was born on January 19, 1869 the son of J. S. Walton and was educated at St. Bartholomew's Hospital taking the M.R.C.S. L.R.C.P. in 1893. Subsequently he took the F.R.C.S. in 1895 the M.B. Lond. (with honours) in 1895, the D.T.M. and H. (with distinction) of Cambridge in 1910 and proceeded M.D. (Gold medal) in the same year. After filling the posts of house surgeon at St. Bartholomew's Hospital and of assistant house surgeon at the Royal Salop Infirmary, Shrewsbury he entered the Indian Medical Service as surgeon lieutenant on July 29, 1896, passing in first. At Netley he gained the Montefiore Prize in Military Surgery and the Martin Memorial Medal in Military Medicine. He became lieutenant colonel on January 29, 1916 and retired on September 1, 1921. He served on the North West Frontier of India in the Tirah campaign of 1897-8 (medal with clasp), the China War of 1900 (relief of Peking actions of Peitsang and Yanglung (medal with clasp)), and in Tibet in 1903-4 (operations round Gyantse, march to Lhasa (medal with clasp)). In May 1905, he was posted to civil employ in the United Provinces and was professor of pathology at King George's Medical College Lucknow, from September 1913 to October 1914 when he reverted to military duty and remained serving in the Army till March 1919. He had been a member of the British Medical Association for twenty eight years.

Lieutenant Colonel JOHN ANDERSON, C.I.E., Bengal Medical Service (ret.) died on May 22 in London aged 52. He was born at Inch Co Donegal on August 4 1882 and was educated at Edinburgh University where he graduated M.B. CM in 1878. He entered the Indian Medical Service as Surgeon on September 30 1878. He became Lieutenant Colonel after twenty years' service and retired with an extra compensation pension on April 1 1910. He served in the Afghan War of 1878-80 was present in the action at Jaddik and received the medal. Most of his service was spent in civil employ in the North West Province, now the United Provinces of Agra and Oudh, where for many years he had the reputation of being the leading civil surgeon in the Province owing to his successful operative work in surgery and held the important civil surgeoncies of Agra and Lucknow successively. He also served for two years as civil surgeon of Simla. After his retirement he served as a member of the Medical Board of the India Office from February 28 1915 to August 4 1920 and received the C.I.E. on June 4 1917. He was twice married first to Mary daughter of the late Mr J. B. N. Hennessy, C.I.E., F.R.S., she died in 1924 and secondly in 1931 to Triphena Esther, widow of the late Surgeon General J. Cl. Horn, C.S.I. and a daughter of the late Major General de S. Barrow who survives him. He had been a member of the British Medical Association for thirty three years.

Lieutenant FRANCIS JOHN SHILKSMITH BAKER, R.A.M.C., died in the military hospital at Jhansi on May 4 from injuries received when a cycle which he was riding came into collision with a tonga. He took the M.R.C.S. LRCP in 1936 and joined the Royal Army Medical Corps as Lieutenant on probation on April 23 1937 so had only a year's service.

## Universities and Colleges

### UNIVERSITY OF OXFORD

Dr A. G. Gibbon has been appointed Litchfield Lecturer in Medicine until June 30 1935.

The Electors of the May Readership have reappointed Dr Alexander Macdougall Cooke as May Fellow and Reader in Medicine to hold office for a further period of three years from October 1.

### UNIVERSITY OF CAMBRIDGE

Acting on a resolution by the Faculty Board of Medicine the General Board recommends that a Readership in Medicine be established for one tenure only and that authority be given to appoint Dr R. A. McCance from August 1 1938. This post would be established in place of the Assistant Directorship of Research recently vacated by Dr J. F. Brock on taking over the chair of medicine at the University of Cape Town. Dr McCance is at present a visiting physician in charge of the Biochemical Department, King's College Hospital, London. The General Board recommends that the regulations be amended to provide that the Reader in Medicine shall not be tutor, assistant tutor, bursar or assistant bursar of a college; he shall not give instruction on behalf of a college for more than six hours a week and he shall not engage in private medical practice. Part of his duties will be to give such lectures as the Faculty Board of Medicine directs.

### UNIVERSITY OF LONDON

Professor C. H. Best, F.R.S. of the University of Toronto, will give a lecture on Heparin and Thrombosis at University College Gower Street, W.C. on Tuesday, June 14 at 5 p.m., when Professor C. Lovatt Evans, F.R.S. will be in the chair. The lecture is open without fee or ticket to students of the University and others interested in the subject.

### UNIVERSITY OF EDINBURGH

Professor C. Heymans of the University of Ghent will deliver a lecture on Some Aspects of Blood Pressure Regulation and Experimental Arterial Hypertension in the anatomy lecture theatre, University New Buildings, Teviot Place, Edinburgh on Friday, June 10 at 5 p.m.

The Cameron Lecture on Results of Recent Studies on Anterior Pituitary Hormones will be delivered by Professor

J. B. Collip, F.R.S. of McGill University, Montreal, in the anatomy lecture theatre, University New Buildings, Teviot Place, Edinburgh on Thursday, June 16 at 5 p.m.

All students and graduates are invited to attend the above lectures.

### SOCIETY OF APOTHECARIES OF LONDON

The following candidates have passed in the subjects indicated:

SURGERY—A. Blackman, F. E. Buckler, R. M. Corker, P. H. Hay, Heddle, T. E. Oor, C. L. Summerfield.  
MEDICINE—W. H. Bayley, P. C. Conran, O. H. Galloway, J. C. B. Nesfield, T. E. Oor, C. Webb.  
FISHERY MEDICINE—P. C. Conran, O. H. Galloway, J. C. B. Nesfield, T. E. Oor, C. Webb.  
PHARMACY—C. V. Arthur, R. M. Corker, J. C. Gregory, C. R. Moton, C. L. Summerfield, W. E. Swanston.

The Diploma of the Society has been granted to W. H. Bayley, A. Blackman, F. E. Buckler, P. C. Conran, O. H. Galloway, P. H. Hay, Heddle, J. C. B. Nesfield, T. E. Oor, C. L. Summerfield.

## Medical Notes in Parliament

The Parliamentary adjournment for Whitsuntide is till June 14.

The business of the House of Lords in the present week included the Coal Bill, the Housing (Rural Workers) Amendment Bill and the Prevention and Treatment of Blindness (Scotland) Bill. The House of Commons considered the Vote for Air Raid Precautions and Bills including the Mental Deficiency Bill. Sir Thomas Inskip made a statement regarding national service in the event of war. He said that in such an event an authority would allocate according to the age and capacity of each individual a suitable position for that person to occupy.

### Progress of Bills

In the House of Lords on May 30 the Coal Bill passed through Committee. The following day the Street Playgrounds Bill passed through Committee and the Housing (Rural Workers) Amendment Bill was read a second time.

On May 31 a Standing Committee of the House of Commons considered the Nursing Homes Registration (Scotland) Bill. A clause moved by Sir Douglas Thomson to exempt from registration nursing homes conducted in accordance with Christian Science principles was withdrawn after discussion on the understanding that it would be reconsidered before the report stage. The Bill passed through Committee and was ordered to be reported with minor amendments to the House of Commons.

### The Scottish Divorce Bill Continued

Consideration of the Divorce and Nullity of Marriage (Scotland) Bill by the Standing Committee of the House of Commons on Scottish Bills was concluded on May 24. On Clause 4 (Grounds for Decree of Nullity) Mr CHAPMAN had an amendment to omit from the grounds of nullity the plea that at the date of the marriage one party was subject to recurrent fits of epilepsy. He said that he would not move these amendments. The whole clause then was deleted from the Bill by 13 votes to 8. Mr ERSKINE-HILL said it was based on the recommendation of the Royal Commission but required more consideration than was possible on the present Bill.

On Clause 6 (Interpretation) Miss HORSBURGH had an amendment to delete the provisions which stated that a defendant in any divorce action should not be held to be incurably insane unless it was proved that he was and had been for a period of five years immediately preceding the raising of

the action under care and treatment as an insane person. The CHAIRMAN suggested that the amendment was out of order in view of the fact that Miss Horsbrugh's earlier amendment to Clause 1 to omit incurably insane had been negatived. After argument Miss Horsbrugh was permitted to move her amendment to omit the relevant Subsection 2 of Clause 6. She said a new clause on the subject of incurably insane was to be moved at a later stage, but she could not see that this new clause fully met the point although it would greatly improve the Bill. Subsection 2 which they were discussing suggested that the definition of incurable insanity was that a person who had been confined under care and treatment in an institution for five years, and where that care and treatment were proved should be presumed to be incurably insane unless the contrary was shown to the satisfaction of the court. She objected to incurable insanity being presumed. Not only were they going further in the Bill than the English Act did by putting the onus of the defence on to an insane person, but they were taking away the safeguards in the English Act. There was a provision in the English Act as to wilful misconduct or neglect by the petitioner which might have conduced to the insanity.

Mr MACQUISTEN said the clause in the Scottish Bill had arisen out of the practical working of the English Act. It had been found that the English medical profession was not prepared to say that any person was incurably insane. It seemed to be wrong that in the Bill Parliament should try to short circuit that difficulty by saying that all that had to be proved was the fact that for five years a person had been under medical care for insanity. The best thing to do was to adopt the English method. Proof should be left to the person who was seeking the remedy. Mr KIRKWOOD and Mr GALLACHER concurred in condemning the provision. Mr ERSKINE-HILL said the clause was essential for the working of the Bill. Mr JOHNSTON said more than the safeguard of medical testimony was wanted. Could the Secretary for Scotland make himself satisfied before an action for divorce on these grounds, not only that the Board of Control had given its imprimatur but that all the circumstances of the case were such that no hardship could possibly occur?

The LORD ADVOCATE Mr T. M. COOPER, said that in actions for divorce on the ground of insanity a curator *ad litem* would be appointed and would be entitled out of the expenses of the husband to have the best medical resources that money could buy to rebut the presumption of incurable insanity if it could be rebutted. In cases where the parties had no money at all the Bill made a provision to bring in the General Board of Control. The words in the clause which said the defender should be presumed to be incurably insane

unless the contrary was shown to the satisfaction of the court meant the presumption would hold if the medical evidence amounted to no more than that the probabilities of recovery were no greater and no less than in any other case of five years continuing insanity. If on the other hand the medical evidence could adduce any assignable reason for

that recovery within a definite period was more probable than in the general run of cases the contrary would be proved. No court of law could attempt omniscience and in this case all the legislature was doing was to set up a certain standard attainment of which would justify certain conclusions unless special circumstances led to the opposite conclusion being sufficiently strongly established. The number of married persons who had been confined in institutions in Scotland for five years at the beginning of the year 1936-7 was about 2,450. In that year twenty-seven married persons discharged cured after being in an asylum for five years included twenty-two who still had spouses alive. Of those who still had spouses alive thirteen were between 50 and 82 years of age and one would not expect them to take a divorce action. The Committee would see that in an average year the number of possible cases to be protected was nine or ten and that the possible husbands or wives who were tied to insane spouses was about 2,450. The rejection of the section under discussion would make the Bill a dead letter.

Mr GIBSON said the figures given by the Lord Advocate materially altered the case.

Sir R. W. SMITH said there were few cases where a person was regarded as insane for the whole time. There were almost certain to be periods when a person in an institution was perfectly sane, and medical officers in charge would never admit that such a person was insane the whole of the time. Persons might be kept in an institution when really for months during the year they might be discharged, and because of that fact they were presumed to be permanently incurable. The person should be examined daily, and if it could be proved that for any period the person was perfectly sane and could be allowed out of the mental institution that should break the five-year period.

Mr CASSELLS pointed out that under the Bill personal service of a divorce petition must be effected on the defender. If service were made in a mental institution the reaction to that would be a most unfavourable one so far as that patient was concerned.

By 20 votes to 5 the Committee rejected the proposal to delete Subsection 2 of Clause 6.

Mr MACQUISTEN moved to substitute seven years for five as the period after which incurable insanity could be presumed. By 16 votes to 9 the Committee reaffirmed the period of five years. The word continuously was added after the word years. On the motion of Mr ERSKINE HILL the Committee accepted an amendment the effect of which was to take out the period where a patient was receiving voluntary treatment for mental illness. He said it covered the case where there was a Scottish husband with a wife in an English asylum.

Clause 6, which also included a definition of the circumstances in which a person should be deemed to be under treatment as an insane person, was then added to the Bill. A new clause was added which provided that it should be the duty of the General Board of Control for Scotland on the request of the court to furnish a report on the probability in the case of a defender to any action under these provisions.

Consideration of the Bill by the Scottish Standing Committee then concluded and the Bill as amended was reported to the House by 16 votes to 3.

### Salvarsan Production in the United Kingdom

Mr DAVID ADAMS asked the quantities and values of the following chemical compounds produced and consumed in the United Kingdom and also in other areas within the British Empire in the most recent year for which figures were available: salvarsan, Bayer 205 trypanamide, atebrian, phismoquin, trypan blue, and trypanflavin.

Mr RONALD CROSS replying for the Board of Trade on May 20 said that during 1935, the latest year for which the information was available the output in the United Kingdom of salvarsan and neosalvarsan and other organo-arsenic compounds of like medicinal application amounted to 7,900 lb of a selling value of £107,000. No other official information was available regarding the output or consumption of the substances specified by Mr Adams in the United Kingdom or in other parts of the British Empire. Imports of the commodities mentioned in the question were not separately recorded in the published trade returns of the United Kingdom. Salvarsan and neosalvarsan and other organo-arsenic compounds of like medicinal application were separately recorded up to the year 1933 in which year imports into the United Kingdom amounted to 69 lb, valued at £3,296.

### Germany's Chemical Monopolies

On May 24 Mr D. ADAMS asked the Chancellor of the Duchy of Lancaster, representing the Lord President of the Council, whether his attention had been drawn to the fact that in case of war the British Empire would be without access to important chemical compounds of which Germany had a virtual monopoly, whether he was aware that German firms producing these chemical agents did not as a rule grant licences for manufacture in this country, and whether any Government action was contemplated in view not only of possible war time

contingencies but of the continuous and urgent need of the British tropical Empire.

EARL WINTERTON said the discovery of new chemical compounds of certain kinds, particularly those which could be used in the treatment of some tropical and other diseases, at present depended largely on research work undertaken by industrial concerns in Germany, with the consequence that large supplies of these new substances could for a longer or a shorter period be obtained only from abroad. It was for this reason that the Government had approved the proposal of the Medical Research Council for expenditure at the rate of £10,000 per annum on research in chemotherapy, to enable this country to play a greater part in future in making new discoveries in this field.

MR ADAMS asked if Lord Winterton was satisfied that this small sum was sufficient for the needs of the situation. EARL WINTERTON replied that since questions were previously asked on this subject he had gone into the matter with the Lord President's Department and the Medical Research Council. There were other grants in connexion with this particular research in addition to this new sum of money which in the first two years would be largely expended in making new premises. The result would be greatly to enlarge the field of research. The matter might be reviewed at some later date.

### Blood Tests for Paternity

In an answer to Mr Sorensen on May 25 MR LLOYD said there had never been any doubt that if each of the parties to a blood test proceedings was willing to submit to a blood test and if the results were admissible. The publicity given to a recent case would make the possibilities of the test more well known to magistrates and others concerned. Legislation would however be required to make blood tests compulsory in cases of disputes as to paternity and the Home Secretary could hold out no prospect of introducing legislation on this subject.

### Civilian Doctors Employed at Recruiting Depots

SIR KINGSLEY WOOD told Sir Reginald Blair on May 25 that civilian medical practitioners employed at Royal Air Force recruiting depots receive an inclusive salary of £500 a year. Two officers in receipt of retired pay are paid at special rates. Appointments are on a non-pensionable basis and are subject to one month's notice on either side. He was considering a memorandum which he had received on this matter.

### Incidence of Silicosis

MR ELLIS SMITH asked on May 26 if the Home Secretary was satisfied with the recently published statistics on silicosis. MR LLOYD in reply said the number of cases was a matter of serious concern and emphasized the necessity for taking all possible preventive measures. Much had been and was being done in this direction. In several industries where ancient precautions had been adopted over a long period of years there was now a marked reduction in the number of cases. It was also to be borne in mind that the disease had developed very slowly and that many of the cases now occurring were the result of conditions existing before the necessary precautions were introduced. The medical board now appeared to be working satisfactorily and no material change was in contemplation. Information was being considered with a view to possible extension of the scheme to some additional processes.

### Typhoid Outbreak at Hawick

Replying on May 26 to Captain ELLISTON who asked what steps were taken to control the outbreak of typhoid at Hawick, MR COLVILLE, Secretary for Scotland, said that from the beginning of the outbreak the local public health authorities in co-operation with the Department of Health for Scotland and the local practitioners used every

means of dealing with the outbreak or preventing its spread and of ascertaining its cause. Ample hospital accommodation for typhoid patients had been secured by bringing into use two buildings not normally utilized for cases of infectious diseases. The necessary bacteriological work involved in such an outbreak had been carried out first in the bacteriological department of Edinburgh University and later in a special laboratory established in Hawick. As a measure of precaution the local water supply was being chlorinated though it had been established that the water supply was not the vehicle of infection. Inhabitants of Hawick had also been advised to boil all milk and water. All contacts had been forbidden to handle food-stuff. The lending library and the public swimming pool had been closed and for a short time the public baths were also closed. In the examination into the cause of the infection exhaustive tests of the milk supply and of the source and distribution of all foods in common use were made and all employees engaged in production and distribution were where necessary subjected to special tests. As a result the cause of the outbreak had been narrowed down to certain foodstuffs and it was believed that most if not all of the sources of infection had been cut off.

*Conditions of Offices*—MR BERNAYS replying on May 17 to Sir Nicholas Grattan Doyle said that the Minister of Health had no reason to doubt that the local authorities were exercising their powers under the Public Health Act 1936 in respect of the conditions of offices in their areas. He proposed to call for reports from them at the end of the year.

*An Impure Milk Supply*—On May 24 MR WESTWOOD asked the Secretary of State for Scotland if his attention had been drawn to the report of the public health authority on the filthy condition of milk which was being supplied to the Milk Marketing Board from the county of Angus and if so what action he proposed to take to safeguard the health of the people from an impure milk supply. MR WEDDERBURN replied that the milk referred to was supplied by a single producer and was not now being accepted by the Board.

*Medical Superintendent of Whiston Institute, Lancashire*—MR PILKINGTON asked on May 26 in what circumstances DR P. G. SAWMY, who was for ten years assistant medical superintendent of the Whiston Institute, Lancashire, had been dismissed. DR ELLIOT replied that the action taken by the county council had been brought to his notice but the matter was one within their sole discretion and not one in which he had any power to intervene or on which he could usefully offer any expression of opinion.

### Notes in Brief

There are 122 European and sixteen African doctors employed by the Government in Nigeria. On the Gold Coast seventy-four European and ten African doctors are employed by the Government. Information regarding non-Government doctors is not available.

In the last twelve months the Glasgow Corporation built 2,118 houses. This figure compares with 2,182 in 1937, 2,903 in 1936, 4,546 in 1935 and 3,360 in 1934.

On May 24 MR Wedderburn replying to Mr Henderson Stewart said he had received no complaints regarding malnutrition among the children of farm workers in Fife.

Four cases of small pox were notified in England and Wales in 1937. No deaths from this disease were registered during that year.

Insulin treatment is being applied in some twelve public mental hospitals in this country.

All school children will be provided in emergency by the Government with respirators which they will carry with them to and from school. Containers will be provided.

A book of the report of the Select Committee on Patent Medicines published in 1914 and reprinted in 1936 remains available through the Stationery Office.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended May 21, 1938

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland Median values for the last 9 years for (a) and (b)

Figures of Births and Deaths, and of Deaths recorded under each infectious disease are for (a) The 126 great towns (123 in 1937) in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns (9 in 1937) in Northern Ireland

A dash — denotes no cases a blank space denotes disease not notifiable or no return available

Disease	1938					1937 (Corresponding Week)					1929-37 (Median Value Corresponding Weeks)

\* 6 cases in Belfast alone

† After October 1 1937 puerperal fever was made notifiable only in the Administrative County of London

‡ Death from puerperal sepsis

§ Includes primary form in figures for England and Wales London (administrative county) and Northern Ireland

## EPIDEMIOLOGICAL NOTES\*

## Enteric Fever

Fifteen cases of enteric fever were notified during the week in England and Wales compared with 14 in the previous week while the numbers for London were 2 and 1 respectively. There were 1 each in Chelsea and Westminster, and isolated cases occurred in Croydon, Portsmouth, Brighton, Reigate. In Scotland 34 cases were notified compared with 30 in the previous week, of these 24 cases of typhoid fever occurred in Roxburgh County and 1 (typhoid fever) in Selkirk, all presumably belonging to the Hawick outbreak. Four cases of typhoid fever were reported in Glasgow and 1 in Airdrie. Three cases of paratyphoid fever were notified in Glasgow the same number as last week and 1 in the County of Aberdeen. The diagnosis in the 4 members of the crew of the Orient liner *Orima* referred to last week as having been admitted to the Port of London Sanitary Hospital for observation has since been confirmed.

## Diphtheria and Scarlet Fever

Notifications of diphtheria in England and Wales showed an increase of 112 over the previous week and in London an increase of 20. There was a decided fall in the number of deaths especially in London. Of the 36 deaths recorded in England and Wales 5 were in Liverpool, 3 in Kingston upon Hull and 2 each in Bolton, Bradford and Bristol. There were fewer notifications of diphtheria in Scotland, Eire and Northern Ireland and each country reported fewer deaths except Northern Ireland where there was 1 death compared with nil in the previous week. Of the Scottish deaths 4 occurred in Glasgow, 2 in Paisley and 1 in Edinburgh. There were 2 deaths from diphtheria in Dublin and 1 in Belfast. Notifications of scarlet fever in England and Wales were 147 nearly 120 and in London there was an increase of 10 over the previous week. Small increases of notifications were noted in Scotland, Eire and Northern Ireland. The notifications in England and Wales remained above the median value for the last nine years while in London they were slightly below it.

## Primary and Influenzal Pneumonia

There was a considerable rise in the notifications of pneumonia (primary and influenzal) in England and Wales and London shared in the rise. Deaths in England and Wales rose from 54 to 66 while in London they dropped from 11 to 10. In the West Riding (Yorks) 171 cases were notified of which 64 were in Sheffield and 7 in Leeds. In Warwickshire there were 78 cases of which 51 were in Birmingham. Of the 210 cases in Lancashire 62 were in Manchester and 49 in Liverpool. Of the 66 deaths from influenza 4 were in Birmingham, 3 in Blackburn and 2 each in Kingston upon Hull, Manchester, Bolton, South Shields, Coventry, Derby, Walsall, West Bromwich, Rhondda, Croydon. In Scotland 252 cases of primary pneumonia were notified compared with 266 in the previous week, there were 8 cases of influenzal pneumonia—3 less than the previous week—and 7 deaths of which 4 were in Glasgow and 1 each in Edinburgh, Kirkcaldy and Coatbridge. There were 16 deaths from pneumonia in Eire of which 9 occurred in Dublin and 13 deaths from pneumonia in Northern Ireland (12 in Belfast).

## Measles and Whooping-cough

In the 126 Great Towns there were 26 deaths from measles compared with 28 in the previous week, of these 10 (11) occurred in London and 2 each in Kingston upon Hull, Manchester, Newcastle upon Tyne and West Hartlepool. During the week 942 cases were reported from

\* Except where otherwise mentioned figures in parentheses refer to the week preceding the one under review.

the 100 elementary schools compared with 843 in the previous week. The average daily admissions to the 100 fever hospitals were 30 compared with 49 in the previous week while the number of cases of measles under treatment in these hospitals on Friday, May 20 was 1364 compared with 1620 on May 13. On the same day there were under treatment in the LCC fever hospital 1070 (1047) cases of diphtheria, 843 (777) cases of scarlet fever, 275 (287) cases of whooping cough. Notifications for the week ended May 21 in the eleven metropolitan boroughs in which measles is notifiable were 348 (461) distributed as follows: Battersea 25 (36), Bermondsey 19 (1), Enbury 19 (19), Fulham 28 (42), Greenwich 95 (120), Hampstead 13 (20), Lambeth 52 (56), St. Pancras 41 (71), Shoreditch 15 (59), Southwark 13 (21), Stepney 28 (27). In Scotland 382 cases of measles were notified compared with 426 in the previous week, the figures for Glasgow were 129 (164), Dundee 63 (77), Aberdeen 36 (60), Falkirk 76 (57), Edinburgh 24 (36). During the week there were 10 (21) deaths from measles in the 16 principal towns of Scotland, of these 3 each occurred in Glasgow (9) and Dundee (7), 2 (0) in Aberdeen and 1 each in Clydebank (1) and Ayr (0). In Northern Ireland there were 2 deaths from measles—1 in Belfast and 1 in Newry. There were no deaths from measles in Eire during the week under review.

In England and Wales whooping cough was responsible for 17 (20) deaths of which 1 (6) occurred in London. There were 5 deaths from whooping cough in Birmingham and 2 in Liverpool. In Scotland 59 cases of whooping cough were notified compared with 97 in the previous week while the deaths remained at 2—1 each in Glasgow and Aberdeen. In Northern Ireland 7 (25) cases of whooping cough were notified with 2 (1) deaths both in Lurgan.

## Cholera

The figures for the incidence of cholera in India (including Burma) for the first quarter of 1938 have come to hand, 53143 cases were notified compared with 42684 for the corresponding period last year. In India itself 33123 cases were notified of which 67 per cent were in Bengal and about 17 per cent in the Presidency of Madras. In the two following months (April and May) epidemics were notified in the Punjab, the United Provinces and the Central Provinces following the Kumbhamela festival at Hardwar (United Provinces) which is held every twelve years. In the United Provinces there have been 7000 cases in six weeks more than half of which proved fatal.

## Plague

In India (including Burma) the provisional number of plague cases notified during the first quarter of 1938—12045—was markedly lower than that for the corresponding period of 1937 when 16465 were notified. The reduction was most marked in the United Provinces and Central Provinces which remain the principal foci of plague in India. Of the 9670 cases in India itself during this quarter 48 per cent occurred in the United Provinces and Bihar and 29 per cent in the Central Provinces.

## Small pox

During the week ended May 21, 21 (26) cases of smallpox were reported in Hong Kong with 20 (25) deaths during the same week there were in the Presidency of Bombay 443 (391) cases with 84 (87) deaths. In Bombay itself there were 27 (38) cases and 22 (23) deaths. In Sind during the same week there were 154 (192) cases of smallpox and 11 (27) deaths. In Tonkin (French Indo China) 93 (122) cases were reported during the same week.

## Typhus

During the first quarter of 1938 3738 cases of typhus were reported in Eastern Europe compared with 5109 in the corresponding quarter last year. The reduction

affected all the countries in Europe where typhus is endemic with the exception of Lithuania and Poland, where increases were recorded. The largest numbers reported were Poland 1,592, Rumania 1,513, Yugoslavia 328. In Morocco during the week ended May 14 175 cases of typhus were reported, with 18 deaths, the principal localities affected were Casablanca 77 cases, 10 deaths, Marrakesh 27 cases, 3 deaths, Rabat 17 cases, 2 deaths, Oued-Zem 17 cases, 3 deaths. In Egypt in the week ended May 6 there were 173 cases of typhus and 13 deaths distributed chiefly as follows: Beheira 50 cases, 2 deaths, Minufiya 33 cases, Gharbiya 14 cases, Cairo 6 cases, 2 deaths. In Tunisia during the week ended May 15 there were 38 cases of typhus distributed chiefly as follows: Tozeur 14 cases, Susa 7 cases, Southern Military Territories 5 cases. The last week for which figures are available from Algeria is the week ended April 30, during which 49 cases of typhus were reported distributed mainly as follows: Oran 16, Bellevue 20, and Constantine 16.

### COMMITTEE ON MENTAL HEALTH

The Council of the British Medical Association at its meeting on June 1 appointed a special committee to study the problems of mental health, including the amount of industrial disability due to mental illness and the need for the extension and improvement of institutional facilities. The proposal that a special committee of the Association should investigate this subject had its origin in a letter published in the *British Medical Journal* of December 18, 1937, in which Dr J. R. Rees, medical director of the Tavistock Clinic, emphasized the importance of improving the existing provision for prevention and treatment of the psychoneurotic and allied disorders.

The committee will make a thorough study of all available statistics, and will seek to compare the importance of mental illness with other conditions already recognized by the State as requiring action. It will consider the part which the general practitioner, hospitals, clinics set up under the Mental Treatment Act, and child guidance and other clinics can play in the prevention of such illness. Careful study will also be made of the degree of success which can be attained with present methods of treatment, and of the type of staff required for the most efficient treatment of in-patients and out-patients respectively. The part allotted to psychological medicine in medical training will occupy an important share of the committee's attention.

The members of the committee are

Sir Robert Johnstone (President), Sir Kaye Le Fleming (Chairman of Council), Dr H. Guy Dain (Chairman of Representative Body), Mr N. Bishop Harman (Treasurer), Sir Henry Brackenbury, Dr J. A. Brown, Professor Millais Culpin, Dr R. G. Gordon, Sir Walter Langdon Brown, Dr Marv C. Luff, Professor E. Mapother, Dr Doris M. Odum, Dr A. A. W. Petrie, Dr J. R. Rees, Dr Benjamin Reid, Dr D. Stewart, and Dr R. M. Stewart.

The annual report of the British Red Cross Society shows continued expansion in respect of both membership and activities. The number of Detachments, men's and women's, has substantially increased and the Society's trained personnel numbers over 30,000 exclusive of Air Raid Reserves. Much progress has been made in special training for co-operation with the Home Office schemes for defence against aerial warfare and also in the training of instructors, whose services are available as lecturers to the general public. County branch reports show the very wide range of services rendered to the public by first aid including first-aid stations on the roads and at seaside resorts, by home nursing and invalid transport by assistance to hospitals and clinics, and through widespread general instruction on matters of health. The report for 1937 includes a summary of the activities of Red Cross Societies and Branches throughout the Empire. It is published from 14 Grosvenor Crescent, London, S.W.1.

## Medical News

Professor E. J. Salisbury, D.Sc. F.R.S., will deliver a Chadwick Public Lecture on Plants in Relation to the Human Environment at the Chelsea Physic Garden, Swan Walk S.W., on Thursday, June 9, at 5 p.m.

Founders' Day will be celebrated at Epsom College on Saturday, June 18. Play on the second day of the cricket match against the Old Boys will start at 11 a.m. At noon there will be a service in Chapel for College and parents at 2.15 in assault arms and at 3.30 Sir Cosmo Parkinson will give away the prizes in Big School followed by tea on the cricket ground.

In our advertisement columns this week the University of Bristol invites applications for the posts of Professor of Pathology and Lecturer in Pathology at salaries of £1,000 per annum and £400-£500 per annum respectively, also the University of Capetown invites applications for the Chair of Physiology at a salary of £1,000-£1,100 per annum.

Dame Florence Barrie Lambert D.B.E. M.B. will present the prizes and certificates to successful students of the London (Royal Free Hospital) School of Medicine for Women on Wednesday, June 15, at 3 p.m.

The twelfth annual meeting of the Swiss Society of Dermatology will be held at Geneva on June 25 and 26, and the annual meeting of the Swiss Paediatric Society at Berne on June 11 and 12.

The Stoke-on-Trent City Council on May 24 approved a scheme for extending the London Road Public Assistance Hospital at a cost of nearly £100,000. The Medical Officer of Health, Dr A. Wotherspoon, told the council that in place of second rate buildings for 755 patients they would have a first class hospital with 890 beds, including 130 for maternity cases. The nursing staff would be increased from 140 to 340.

The April issue of the *Bulletin de l'Office International d'Hygiène Publique* contains articles on immunity to small pox, post-vaccinal encephalitis in Germany, England and Wales, Italy and Sweden, and pulmonary tuberculosis in Belgium, Denmark, the United States, Germany, Italy, England and Wales, and Sardinia.

The Lord President of the Council has appointed Professor R. H. Fowler, F.R.S., at present Plummer Professor of Applied Mathematics in the University of Cambridge to be Director of the National Physical Laboratory, with effect from October 1, 1938. Professor Fowler will succeed Dr W. H. Bragg, who has been elected to the Cavendish Professorship of Experimental Physics in the University of Cambridge.

Dr L. A. Hurst, of the Department of the Interior, Government of South Africa, has been awarded a Commonwealth Fund Fellowship in Medicine tenable at the New York State Psychiatric Institute.

Colonel Cecil Birt, late A.M.S., who died on March 18, left an estate of the gross value of some £35,000. He bequeathed all his property subject to life interests to the Library Endowment Fund of the Royal Society of Medicine. Colonel Birt was a regular user of the library, and we are informed that his bequest was made spontaneously as an appreciation of the services which the library renders to Fellows. It is hoped that this example may be followed by others who recognize the value to science and medicine of a first class medical library.

The King has appointed Dr Arthur Hutton McShine to be a Member of the Executive Council of the Colony of Trinidad and Tobago.

Chairs for occupational diseases are to be founded in the universities of Czechoslovakia.

Professor F. W. O'Connor, who died on October 2, left his scientific books, papers, photographs, equipment, and 64-acre farm at Branchville, New Jersey, to the New York Academy of Medicine.

# Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are held in good to be offered to the *British Medical Journal* unless the contrary be stated. Correspondents who wish not to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1 on receipt of proof. Authors overseas should indicate on '155' if reprints are required as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager. Orders for copies of the *Journal* and communications with reference to subscription should be addressed to the Secretary, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

THE TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is ELSTON 2111.

TELEGRAPHIC ADDRESSES are:  
EDITOR OF THE BRITISH MEDICAL JOURNAL: MEDIC (L)  
B.M.A. HOUSE, LONDON.

SECRETARY: MEDUSCRA, WEST CENT, LONDON.

The address of the B.M.A. Scottish Office is 7, Dumbarton Road, Edinburgh (telegrams: ASSOCIATE, EDINBURGH). The address of the B.M.A. English Office is 1, The Strand, London (telegrams: ASSOCIATE, LONDON). The address of the B.M.A. Irish Office is 1, Kildare Street, Dublin (telegrams: BACILLUS, DUBLIN; telephone 62550 Dublin).

## QUERIES AND ANSWERS

### Cancer and Smoking

Lieutenant-Colonel H. H. KING CBE M.S. (ret.) writes: A propos of the possibility of preventing cancer, are there any statistics available of the relative incidence of cancer in smokers and non-smokers? If the constant slight exposure of a tissue to a diluted carcinogenic substance definitely promotes the occurrence of cancer—as appears to be likely—then it would be advisable to ascertain whether in fact this is the case, and I suggest that this comparison would give us valuable information, particularly if it was divided into two portions: (1) cancer of the mouth, tongue and respiratory passages; (2) cancer elsewhere.

### "Typhoid Mary"

Dr J. D. ROLLESTON writes: In reply to my query in the *Journal* of April 23 (p. 932) Dr J. Rosslyn Earp, Medical Editor, Department of Health of the State of New York, has kindly sent me the following information: Dr Sebbins, the Director of the Division of Communicable Diseases in this Department, tells me that following her application in the Sloane Maternity Hospital outbreak, Mary Mallon was confined to Riverside Hospital on North Brother's Island continuously until her recent death. In so far as can be determined there is no evidence of her having caused cases since 1915. He also recommends an account of Typhoid Mary, published in the *New Yorker* of January 23, 1935. This account he tells me is quite accurate though not too solemn.

### Mosquito Bites

Dr E. B. LATHBURY (London EC2) suggests the following prescriptions: (1) of eucalypt 2 oz. ac carbol liq. 4 drops, oil citronella 2 oz. mix and apply a few drops on face and face. (2) Oil cassia 1 oz., brown oil of camphor 2 oz., vaseline lanoline or salad oil 3 oz. smear on the skin in small quantities.

Miss M. W. REEVE writes: The late Lieutenant Colonel R. H. Elliot (with whom I was for ten years) always used oil of lavender 1 part citronella oil 4 parts alcohol 1 part. This was put in a throat spray and kept in his car. He was fond of going for picnics, and as soon as he got out of his car he and anyone with him sprayed their legs and wrists. I remember this was repeated an hour or two later. Colonel Elliot was very badly affected by insect bites, and he never had any trouble after using this mixture. I have made it up for him many times.

## Alopecia

Dr J. M. DOTAN (Cumberland) writes in reply to R. J. C. (10th May 14, p. 1084): I have had similar cases at intervals from 15 to 45 years in all of which the patients were otherwise perfectly healthy. I adopted the following line of treatment with success in each case. I give each case a third degree dose of ultra violet light on the affected area and this is repeated at weekly intervals until the condition is cured. If the area is too large I divide it up and give a third degree erythema dose on no more than three areas the size of a coin piece in one week. These areas are also irradiated at weekly intervals. If the case seems more resistant than usual I put the patient on some form of mixed glands daily in addition to the usual ultra violet treatment. It is to be noted that the skin of the scalp requires a longer exposure to the light to produce a third degree erythema than the skin of other parts of the body.

## An Internal Sanitary Pad

W. B. writes: I am rather surprised that the recent correspondence in your columns on this subject should have been in the main unfavourable because several of my patients who have been using this sanitary pad for some months now have been very satisfied and have given up the use of the orthodox external pad. So much so that in stead of advising against it when asked as your other correspondents have done I have kept an open mind about it until more comprehensive results are available and have advised each patient to try it for herself. One fact at least is evident—that most women welcome the idea of a vaginal pad since however much they may be used to the external pad they are always conscious of its presence and even if in some cases there is no actual discomfort or labial chafing no one can say that it is really comfortable.

## LETTERS, NOTES, ETC

### A Twelfth Century Case of Miscarriage

Dr GILBERT W. CHARSLEY writes: In the *Journal* of May 28 (p. 1157) I read with interest Dr Annie Svidenham's memorandum on 'An Unusual Case of Miscarriage'. To add further interest perhaps I may be excused for quoting from a book *The History of Physick from the Time of Galen to the beginning of the 16th Century* written by J. Freind, M.D. and printed in 1727. In this book Dr Freind refers to Albucasis, an Arabian surgeon of the twelfth century who stated the following case of a woman who had a child which died in the uterus and after was pregnant again the second conception died too. Some time after an abscess broke out at the Navel from whence to the great surprise not only pus but bones came out. Upon reflection he found they were the bones of a Foetus and he took a great many of them out. The woman lived many years after but had a continual running Ulcer at that place. However strange this story may appear the experience of the moderns furnishes us with several parallel instances, one particularly where the Woman not only recovered but lived to have a child after.

### Food Contamination by House-flies

Dr W. B. HOWELL (Devon) writes: Now that a campaign for national fitness is on foot it is to be hoped that some effort will be made to awaken the people of England to the danger to health of house flies through food contamination. The Americans are far ahead of us in this matter. In England it is as rare to see windows screened against flies as it is common in the United States. In the English countryside farmyards are allowed to exist among residences, and close to them without anything being done to keep the flies out or to kill them at their breeding places.

### Mental and Physical Poise

Dr R. HUNT COOKE (Hendon) writes: The National Health and Fitness Campaign is one which should appeal in a great degree to the medical profession as it is compatible with the strides which are being made in preventive medicine. I was greatly impressed with the work of the Greek Dance Association at its demonstration at the Scala Theatre on May 21. One of the aims of this association is the attainment of mental and physical poise. The dances

are made up of normal movements carefully thought out to avoid muscular overdevelopment and strain and to develop control strength and grace. Repose, relaxation and rhythm are considered to be of great importance all of which are necessary to counteract the effects of modern living. This form of exercise should be of benefit to any type of person especially to neurotic subjects, as it possesses so much rhythm and teaches the expression of individuality. The classes are graded to suit both the mental and physical ability of pupils and all the teachers are people of education and culture with a knowledge of anatomy.

### Medical Work in Newfoundland

The great diversity of the medical and other philanthropic work carried on by the Grenfell Association of Great Britain and Ireland is well illustrated by its annual report for the year ending September 30 1937. The St Anthony Hospital, which began to function in 1902 dealt with 830 patients in the year under review the majority of these requiring general surgical treatment and medical care for conditions other than tuberculosis. Cases of pulmonary tuberculosis numbered 49 of malnutrition 45, and of surgical tuberculosis 20 while there were 75 obstetrical cases including 36 normal and 21 operative deliveries. Beri-beri of which there was a large number of cases for many years is rapidly decreasing in spite of the fact that the economic situation of the population of Labrador and Northern Newfoundland is probably worse than it has been for a long time. Many more families have gardens now and educational work regarding diet has been continuing steadily. The Government has also insisted that all persons receiving relief shall use a more nutritive flour instead of white flour. The increase in tuberculous cases is partly accounted for by earlier diagnosis. The most serious problem is whether the hospital should assume the treatment of the more hopeless chronic cases each of which costs the institution several thousand dollars a year. The St Anthony Hospital provides treatment for the population of an immense area extending from Cape St John on the east coast of Newfoundland to Port Saunders on the west coast and along the Strait of Belle Isle. There are two Government nurses in White Bay, one Grenfell Mission nurse at Englee on the east coast, a Government nurse at Port Saunders and two Mission nurses at Flowers Cove on the west coast. The hospital ship *Strathcona* with a doctor and a dentist visited every settlement in the White Bay district during the summer, and removed to hospital all persons needing in-patient treatment or special supervision. Dr T G Hood describes the work of the Harrington Hospital where pulmonary tuberculosis is the outstanding problem. It is remarked that thyroid disease is extremely rare in Labrador so far as the coast is concerned, though more common in the interior. The general interest of the report is enhanced by an account of the industrial handicrafts work of the Mission which is of great value economically and provides occupation for the long winter periods. Reference is repeatedly made to the friendliness, cheerfulness under difficulties and gratitude of these people.

### Use and Abuse of Antiseptics

Dr A C F HALFORD writes from Brisbane. I have been a laboratory worker and a clinical surgeon and I try to hold my experience in both spheres in their proper perspectives. It is from both points of view that I have disagreed with Mr Norman C Lake (*Journal* April 2, p 753) and I am convinced that neither laboratory tests nor clinical use justify us in giving spirit solutions of biniodide of mercury a place anywhere. Especially is this so in minor surgery. My real purpose in writing on any phase of surgical and midwifery practice is to draw serious attention to the undue prevalence of sepsis in spite of Mr Lake's claims of the hundreds of thousands of operations he mentions. The surgeon who uses only hot water and soap has been known to make the same claim but there are many wounds that break down and the fault is not merely the choice of antiseptic many are chosen but few used wisely. It is the protection of a wound against exogenous infections—cross infections and secondary infections—that worries us a position to day that is approached by the younger practitioners especially with hope but not with certainty. Why does the laboratory worker not step in and say that a wound dressed with no antiseptic protection at all cannot be safe any more than the soiled sterile plug of a tube of culture liquid can prevent contamination of the whole? Thus is it that I

continue to write protesting against inefficient lotions and aseptic dressings and plead for a return to intelligent antiseptic measures.

### Ophthalmology in Palestine

In spite of the unsettled conditions in Palestine the progress made by the Ophthalmic Hospital of St John of Jerusalem in 1937 was most satisfactory. The number of new out patients, 21 367, was the largest on record, and the out patient attendances reached the remarkably high figure of 108 616. The number of in patients 907, was below that for the previous year. The annexe was as full as usual and there was a daily average of 100 patients in the arcades of the khir. Training in ophthalmology of the Palestinian nurses continued efficient and popular. It has been decided to build a new block for paying patients and for a physio-therapeutic department on the south side of the existing buildings, the appeal for funds having resulted in the receipt of over £10,528. Many patients were received from the Army and the Royal Air Force. A slight earthquake shock towards the end of the year under review opened up the cracks in the roofs and all leaked badly during the November rains with the exception of the large dispensary roof which had previously received special asphalt treatment. The question of treating all the roofs in this manner is now being considered carefully. Sir Horace Rumbold, Vice Chairman of the Palestine Commission described the hospital as the finest piece of British propaganda in the East. The electric lighting, heating and power supply of the institution has now been undertaken by the Jerusalem Electric Corporation at a reasonable flat rate. The civil disturbances in Palestine interfered with road transport and diminished the attendances by the peasantry, as contrasted with the local town population. The number and percentage of Jewish patients increased more particularly. The incidence of trichoma among the new patients 8.82 per cent, was the lowest hitherto recorded at the hospital, indicating a temporary change in the character of the patients, there being more urban dwellers, among whom this disease is relatively less common. Some improvement was noted in the blindness rate in spite of a severe but localized outbreak of acute conjunctivitis affecting the townspeople. Potent factors in this outbreak were malnutrition debilitation due to measles and whooping cough, and the widespread economic distress consequent on unemployment. These cases do not respond well to treatment.

### Sedimentation Tests in General Practice

Dr A E FINCKH (Sydney) writes. Any general practitioner wishing to employ the blood sedimentation test may find the following technique a great advantage. Use oxalated blood as for blood sugar examinations. Of a 10 per cent potassium oxalate solution put one drop on the bottom of a small bottle. Heat gently till evaporated to dryness. Keep a number of these in stock. Collect from 2 to 3 ccm of blood from a vein and deposit in the oxalate bottle. Shake gently. Take a graduated 1 ccm pipette and suck up to near the 0 mark and block with the finger. Block the other end by stabbing into a cake of soap or wax. Keep vertically at room temperature and read off in an hour.

### Medical Golf

There were nearly a hundred competitors for the Manchester and District Medical Golfers' Association annual competition held on the Northenden links on May 25. The challenge cup for medal play was won by Dr J G Stewart of Oldham with the best net score of 67. Dr Stewart also won the Walter silver medal for the best gross score from a handicap of 10 or over. Dr W L Hunter of Hale won the Walter gold medal with the best gross score of 73 and Dr J S B Mackay of Bury won the captain's second prize. A prize for the best net score over the first nine holes was won by Dr J E R Keyms of Fairfield, and another for the best score of the second nine holes by Dr L J O Loughlin of Moss Side. Play was over eighteen holes, and the weather was favourable.

### Corrigendum

In Epitome paragraph No 398 on sulphathiazide in cerebrospinal fever, which appeared in the *Journal* of May 14 at page 80. The dosage was graduated from an upper limit of 15 grammes every four hours. Should have read. The dosage was graduated from an upper limit of 15 grains every four hours.

# EPITOME OF CURRENT MEDICAL LITERATURE

## Medicine

### 453 Family History of Tuberculosis

D MURRAY LYON and W C REID (*Educ Med J* March 1938 p 213) have reviewed 1411 cases in which there was a family history of tuberculosis with special reference to life assurance. The records cover a period of fifteen years between 1921 and 1936. Phthisis accounts for only about 2 per cent of deaths among the general body of assured lives while in their series of cases 20 per cent of the eighty-two deaths were due to tuberculosis. The additional mortality is most marked at ages up to about 35. A family history of tuberculosis does not appear to have any significance from the assurance point of view when the proposer is over that age and is medically examined at the time of assuring. After the age of 35 provided there are no adverse features the question of whether the proposer is a little under the average weight does not appear to be of great importance.

### 454 Intestinal Tuberculosis

F TISELL (*Svenska LakSallsk. Handl.*, Bd 63 Nr 3 1937 p 149) has examined 178 cases of pulmonary tuberculosis with special reference to the detection of intestinal tuberculosis. It was found in fifty-four out of sixty-one cases examined post mortem and was located in every case but one in the ileo-caecal region. Such clinical evidence of intestinal tuberculosis as colic and loose stools proved unreliable for they were absent in 40 per cent of all the cases in which intestinal tuberculosis was radiologically demonstrable. Such general signs as a high temperature and a rapid sedimentation rate were of comparatively little value as they might well be due to the pulmonary disease. The benzidine test for blood in the faeces and Triboulet's reaction for albumin in the faeces proved of little value and the author comes to the conclusion that the most effective means of demonstrating ileo-caecal tuberculosis is by x-ray examination. Radiological evidence is less reliable in tuberculosis of the small intestine but this is rare. With regard to the prognosis the author notes that after an observation period of two and a half years 80 per cent of all the patients showing radiological evidence of intestinal tuberculosis were dead. But this high mortality must, in his opinion, be traced to the serious character of the pulmonary disease. In about one-third of the cases in which intestinal tuberculosis was radiologically demonstrable the interval between the outbreak of the pulmonary and the intestinal tuberculosis was probably less than six months.

### 455 Intermittent Claudication

F KISCH (*Wien Arch inn Med* February 28 1938, p 71) describes a simple standardized work test in connection with intermittent claudication. It consists in the rhythmic repetition—at the rate of thirty movements a minute—of maximal flexion followed immediately by maximal extension of the lower limb at the ankle, knee, and hip-joint. The movements are repeated until the characteristic pain of intermittent claudication makes its appearance. The author claims after observing fifty-three cases that this test may advantageously be used for determining the degree of claudication present at the beginning of treatment and for estimating the success or otherwise of the treatment adopted. The object of the treatment is to promote the establishment of as satisfactory a collateral circulation as possible. According to Kisch this may best be done by a combination of three factors: (a) the use of drugs as nitroglycerin, caffeine etc., and alcohol in

the form of brandy or whisky; (b) as much rest as possible for the affected limb and the avoidance of all harmful influences such as pressure, cold, heat and injury; (c) the exercise of the greatest care in ensuring the healthy function of the digestive system and the massive administration of fluids. Kisch states that the results obtained by treatment of his cases along these lines were very good in 45 per cent of cases, moderate in 20.2 per cent and no improvement was observed in 24.5 per cent.

### 456 Heart Damage after Diphtheria and Rheumatism

A VON DOMARUS (*Med Welt* January 1 1938 p 1) points out the difficulty of assessing the amount of myocardial damage present in patients with a history of diphtheria or rheumatism. Diphtheria attacks the myocardium chiefly rheumatism the endocardium. Fewer cases of myocardial damage due to the former are met with on account of the high mortality of malignant diphtheria. Diagnostic methods for the assessment of myocardial damage include radiography, auscultation, electrocardiography and estimation of the blood pressure. The shape of the heart on x-ray examination and the changes seen in the electrocardiogram are important. Nervous patients should be re-examined after some weeks of rest with the administration of bromide and valerian. Observations as to the general condition of the patient are of more value than a single low blood pressure reading. The heart's function may be assessed by the rapidity of the pulse before and after exercise and by the combined control of the pulse, electrocardiogram and blood pressure with the patient recumbent and standing and before and after exercise. Latent myocardial damage may be revealed by a marked polyuria following a single intravenous injection of 0.3 mg of strophanthin. Finally the carefully controlled effect of games, gymnastics and military exercises on the heart is of value in assessing the degree of damage. All sources of focal infection must be dealt with. Times of rest and relaxation must be carefully prescribed and adhered to. Medicinal treatment is of little value except in rare cases. Spa treatment is often beneficial. Alcohol, tobacco, tea and coffee should be forbidden. Any subjective symptoms referable to the circulatory system are contraindications to the resumption of activity. When these have disappeared a gradual return to normal life should be encouraged.

## Surgery

### 457 Primary Carcinoma of the Male Urethra

E A MILLER (*Urol cutan Rev* February 1938 p 88) describes carcinoma of the urethra as a rare condition. It is usually seen in men over 50 although cases have been recorded at an earlier age. The lesion generally arises from the bulbous urethra and stricture occurs in at least 50 per cent of cases. Various causes are suggested the most common being trauma and leukoplakia probably resulting from chronic urethral infections. The symptoms are obstructive in nature and may be divided into four stages: urethral discharge, dysuria and retention, local tumour formation, periurethral infiltration with urine, and fistula formation. In a few cases bleeding has been an early sign and these are the ones in which operative relief has been achieved. Treatment of urethral carcinoma usually only gives symptomatic relief. 79 per cent of patients live less than six months after the diagnosis has been made. In advanced cases with severe infection, hopeless infiltration and metastasis only palliative treatment can be given. When the bulbous urethra

is involved external urethrotomy with excision and cauterization may be attempted. When the pendulous urethra is the portion involved amputation of the penis has been the operation of choice usually with extirpation of the inguinal glands. Deep x-ray therapy should be given after operation. Tumours at the meatus may be treated by electrocoagulation and radium. A case is reported in which a man of 78 had a nodule in the penis behind the fossa navicularis and along the corpus spongiosum. This tumour increased rapidly in size and two further small nodules became palpable in the distal third of the corpora cavernosa. Palliative measures were unavailing, and the patient died within a fortnight of cardiovascular and renal disease secondary to the urinary obstruction.

#### 458 Early Diagnosis of Gastric Carcinoma

W THIELE (*Med Welt* February 19, 1938, p 266) reviews the different diagnostic methods for the early detection of gastric carcinoma. Pyloric carcinoma is met in about 42 per cent of all cases of carcinoma of the stomach, carcinoma of the body is found in about 32 per cent, carcinoma of the cardia in about 20 per cent, and scirrhous carcinoma in about 5 per cent. In view of the operability of the relatively frequent pyloric carcinoma, an early diagnosis of the condition is of the utmost importance. Unfortunately in 55 per cent of cases reviewed the growth was inoperable by the time the diagnosis was made and 26 per cent of the cases operated on died shortly after the operation. The author is inclined to accept the view that carcinoma of the stomach develops on the basis of chronic gastritis, 5 to 8 per cent of the patients had gastric symptoms for at least a year and 6 per cent for as long as ten years. As to age, 81 per cent of the patients were over 50, and only 6.7 per cent were under 40; the youngest patient was 28 years old. Achlorhydria was found in 65 per cent of cases, hyperacidity was found in 11.5 per cent of cases, but in no case of carcinoma of the cardia, the absence of lactic acid did not exclude carcinoma. The rate of blood sedimentation was altered in only 33 per cent of cases. The general appearance of the patients often proved deceptive, but most of them looked too young for their age. Hereditary predisposition was found in only 23 per cent of patients, the blood pressure was usually relatively low. Occult blood was almost always present in the stools. The blood calcium was usually considerably lowered (often below 10 mg per 100 c cm). Macrocytosis may appear before the usual anaemia and anisocytosis, only 65 per cent of the cases presented anaemia, and 91 per cent of the anaemias were of the hypochromic or secondary type, only 6 per cent being of the hyperchromic type. There seemed to be some relationship between pernicious anaemia and gastric carcinoma.

#### 459 Multiple Enchondromata

B COSSAR (*Polichinico Sez Piat*, March 7 1938, p 434), who records two illustrative cases in a man aged 25 and a boy aged 8, states that enchondromata may be central or peripheral according to whether the centre or the periphery of the bone is attacked. When they arise from the central part the bone increases in size and loses its shape, and the cortex becomes thinned until it breaks. On the other hand, when the growth is implanted in the periphery underneath the periosteum the bone appears to be almost unaffected and the tumour adheres to the bone by a wide base. Most enchondromata develop in the shafts of the metacarpals, metatarsals, and phalanges. They may also be found in the epiphyses of the long bones, such as the humerus, ulna, radius, femur, tibia and fibula. Most writers regard the condition as hereditary. Anatomically enchondromata consist of adult cartilaginous tissue arranged in the form of round or oval nodules, of various sizes well defined and encapsulated. It is generally agreed that the tumour remains stationary once growth has ceased; secondary changes may occur, however, such

as fatty degeneration, vesicular or mucous transformation, ossification or even malignant change. Operation should not be performed until growth has ceased.

#### 460 Bilateral Stellate Ganglionectomy

E SCHNIDER (*Zbl Chir* February 19, 1938, p 402) reports a case of Raynaud's disease in a woman aged 26. After all conservative therapy had failed it was decided to extirpate the stellate ganglia in two stages. Under general anaesthesia both hands became warm, one ganglion was removed at the first operation. The corresponding hand remained warm after operation, while the other hand was blue and cold. This hand improved after the extirpation of the corresponding ganglion at a second operation. For a short time after each operation there was a transitory Horner's syndrome, which cleared up after some eight to fourteen days. Recovery was uneventful and the improvement was lasting. The patient is now able to perform her usual household duties without discomfort, although the hands still become cyanosed on immersion in cold water. Both extirpated ganglia were examined histologically, and appeared normal.

#### 461 Resection of the Elbow-joint

A DAVIDSON and M HOROWITZ (*Surgery* February, 1938, p 226) discuss the relative merits of resection of the elbow joint and arthroplastic reconstruction. Arthroplasty aims at the interposition of a layer of fascia or membrane and the reconstruction of the bone ends so as to adapt the opposing surfaces and give stability as well as movement to the new joint, but may lead to ankylosis again. Resection of the elbow-joint is the operation of choice in cases of adult tuberculous arthritis, and is also indicated in ankyloses of all types—fibrous or osseous, and traumatic or infectious in origin. It should not be carried out after pyogenic infection until several years of quiescence have elapsed, and is inadvisable in cases of ankylosis due to rheumatoid arthritis. Resection is of value also in rehabilitation after elbow-joint fractures with deformity and disability, and in chronic irreducible dislocations. The operation is also indicated for the extirpation of benign and locally malignant osseous tumours. Resection is best delayed until the cessation of period of growth, to avoid a shortened extremity and also re ankylosis. Ollier's method of resection aims at the removal of the bone alone, leaving the periosteum to admit re formation of all the structures of the joint. The good results which follow this operation depend upon a liberal excision of bone and the early mobilization of the new joint. The technique of the operation is fully described. It has been found that active flexion is obtained in two to three months, but complete recovery does not take place in less than six months—that is, until the soft structures have adapted themselves to the resection, then lateral instability grows less marked. A residual 10 to 15 degrees of lateral movement usually persists. In a series of seventeen cases the result was excellent in eleven instances, of which nine were in adults and two in children. In two children a partial restoration of function occurred, and in three more there was ankylosis.

#### 462 Sport Injuries to the Wrist

W WEISS (*Dtsch med Wschr* March 4, 1938, p 340) reports from the University Hospital of Frankfurt a M observations on sport injuries to the wrist. He begins with the general statement that sport injuries involve the upper limbs in about 22 per cent and the lower limbs in about 60 per cent of cases. About half of the injuries to the upper limbs involve the hands and wrists, by far the most common lesion being sprain of the wrist. Of all sprains, this is second only to sprains of the ankle in frequency. He calculates that after fracture of the radius fracture of the scaphoid is the most common of all the bony injuries in or about the wrist, and he quotes

Schnelz as finding that recent fractures of the scaphoid constitute between 3 and 4 per cent of all the fractures of the limbs and between 50 and 60 per cent of all the injuries to the wrist. In the order of frequency of injuries to the bones of the carpus are fracture of the scaphoid, dislocation of the semilunar and fracture of the semilunar. With regard to the diagnosis and treatment of recent sport injuries to the wrist the author insists on the taking of radiographs in at least two different planes and he is an advocate of non operative methods of treatment provided the case is early and the correct diagnosis is made. In his opinion removal of even a single bone is liable to change the static conditions of the wrist to such an extent that there is grave risk of its subsequent usefulness being impaired.

#### 463 Intestinal Obstruction due to Gall stones

E. GASPARI (*Brit. Clin. Chir.* March 1938 p 214) reviews the diagnosis and treatment of acute intestinal obstruction due to gall stones. Three clinical types are differentiated. The acute form of the disease will usually be diagnosed as acute obstruction of the small intestine. Rarely can the obstructing stone be seen radiographically. The remitting type is the one most commonly met with and with this form the patient may have attacks of obstruction lasting for some hours and followed by varying periods of comparative comfort for weeks. Occasionally it will be possible to palpate the stone by rectal or vaginal examination. In the third form symptoms may appear very gradually and simulate the type of obstruction met with in growths of the large bowel. The passage of the stone through the duodenal fistula is not accompanied by symptoms in the vast majority of cases. Should the stone reach the bowel by a dilated common bile duct however, its passage through the ampulla of Vater will cause acute colicky pain. Early operation is essential. The author favours a low lateral incision which will enable the surgeon to palpate the caecum at once. Massaging the stone into the dilated proximal segment of the gut will avoid injury to the already damaged portion. Next the stone will be palpated, and should it be faceted, further search must be made for the presence of other stones. After the stone has been removed by enterotomy treatment will depend on the state of the bowel and the general condition of the patient. The mortality varies between 13 per cent and over 60 per cent. The author has found thirteen cases in the literature in which a recurrence of the condition took place. It is interesting to note that four of the author's eight cases gave no history of preceding gall bladder trouble. Attention is drawn to the fact that at operation or necropsy the gall bladder will often be found to be contracted.

#### 464 Benign Tumours of the Knee

A. BONACCORSI (*Polichinco Sez. Chir.* March 15 1938 p 105) who records an illustrative case states that benign tumours of the knee such as lipomata fibromata chondromata, and myxomata, are by no means common. In almost all the cases on record the tumours were connected with the joint. In his case however which occurred in a man aged 55 following a severe contusion of the knee due to a fall the tumour which was a large fibrolipoma situated on the antero superior aspect of the knee in the subfascial space above the patella was not connected with the joint. Complete recovery followed removal of the growth under local anaesthesia.

#### 465 Pseudo-uraemia of Prostatic Hypertrophy

V. ANASTAS (*Ugeskr. Laeg.* March 10 1938 p 245) challenges the conventional opinion that the patient with prostatic enlargement must be threatened with genuine uraemia when on admission to hospital he complains of thirst loss of appetite nausea headache and certain

other phenomena commonly associated with a high concentration of urea in the blood. Systematic investigations at his hospital have shown that this alarming clinical picture is often in reality due to an acidosis the correction of which in most cases speedily restores the patient to a condition in which operation is possible. Quantitative analyses of the chlorides and bicarbonates in the blood were first systematically undertaken at the author's hospital in surgical cases whenever the clinical picture suggested something amiss in this direction in 1934. Since the beginning of 1936 this examination has been undertaken in all cases of prostatic enlargement both before and after operation. Information thus obtained has been of far greater diagnostic and therapeutic value than was anticipated at the outset. By combating this nephrogenic acidosis by the intravenous injection of an isotonic (13 per cent) solution of sodium bicarbonate it has been possible to operate on seventy seven out of 112 cases of hypertrophy of the prostate within ten days of admission to hospital—usually within only four to five days of admission. Not only did this alkaline treatment shorten the pre-operative period but it also proved useful in many cases in the treatment of serious post-operative complications such as haemorrhage and ascending infection. Since the beginning of 1936 the author has observed nephrogenic acidosis in thirty nine out of 123 cases of hypertrophy of the prostate. He has repeatedly found that a high blood urea concentration irresponsive to catheter treatment and saline infusions did not represent genuine uraemia but an anhydraemia. He sounds a note of warning with regard to an overdosage of alkalis, which may give rise to tetany.

## Therapeutics

#### 466 Sulphanilamide in Streptococcal Infections

P. O. HAGEMAN and F. G. BLAKE (*Amer. J. med. Sci.* February 1938, p 163) record their observations on the use of sulphanilamide in the treatment of 114 cases of infection with haemolytic streptococci. These included cases of erysipelas meningitis otitis media and other conditions. In most instances they found that the drug favourably modified the course of the disease but that it was far from being non-toxic. Complications observed were cyanosis drug fever with or without rash nitrogen retention, hepatitis secondary anaemia and thrombocytopenia.

#### 467 Autohaemotherapy in Hypertension

P. E. PERRET (*Schweiz. med. Wschr.* March 12 1938 p 265) reports his results in the treatment of hypertension by autohaemotherapy. His routine method is to give ten to fifteen injections of 10 c.c.m. of the patient's own blood at intervals of three to four days. In resistant cases he gives a further course of ten injections of 20 c.c.m. with the same intervals. He has treated twenty cases. He finds that in hypertension generally the subjective symptoms have no direct relation to the height of the blood pressure. The symptoms probably depend on other factors such as the rapidity of changes in the tension or in the intracranial pressure. As a result of this form of treatment there is a marked improvement in the subjective symptoms. Patients sleep better and memory improves. Headaches disappeared in 80 per cent of cases usually after the first series of injections. Dizziness and a tendency to fall disappeared in 65 per cent. The effect in cases of tinnitus was disappointing only 20 per cent of cases being relieved. There was little change in the actual blood pressure in some cases it was slightly lowered and in three cases it was actually raised during treatment although the results as regards subjective symp-

tion is shown. There would appear to be a safe period for most women, but owing to the variability of ovulation time and possible multiple ovulation it is extremely difficult to detect it. In their own cases only 20 per cent of women menstruated with sufficient regularity to be candidates for safe-period instruction, and even in these cases according to the Latz-Reiner contraindications, the method is not reliable after confinements, miscarriages, illnesses, or shocks. The very people who most need a fool-proof contraceptive method for medical indications, or because of poverty, are those who are least capable of keeping accurate menstrual records or exercising self-control for the periodic continence. The writers therefore conclude that a small proportion of women will find the safe period with or without the use of a spermicidal jelly, satisfactory for their mode of living, but this method is by no means ready for general utilization.

#### 482 Cystographic Diagnosis of Placenta Praevia

K. JABLONSKI and E. MEISELS (*Zbl. Gynäk.* March 3, 1938, p. 532) comment on the uncertainty of diagnosis of placenta praevia by vaginal examination, which may also increase the dangers of infection and bleeding. They report their results in diagnosis by vesical cystography, as recommended by Ude and Urner (*Amer. J. Obstet. Gynec.* 1935, 29, 667). The bladder, photographed from the front after the introduction of 40 ccm. only of radiopaque solution, gives a flattened shadow with an upward concavity, normally its upper margin is in contact with the lower vertical convexity of the foetal skull or separated from it by not more than 1 cm. In cases of placenta praevia the distance between the bladder and skull shadows is greater than 1 cm. Jablonski and Meisels report a general confirmation of the findings of Ude and Urner with respect to central and lateral placenta praevia, the diagnosis positive or negative, was correct in thirteen cases of ante-partum haemorrhage. A marginal placenta praevia, however, especially if inserted on the posterior uterine wall, does not give a positive result with this test. The separation between the bladder and foetal head may be mimicked (1) according to some authors by the accumulation of blood clot in premature detachment of the normally situated placenta, (2) in early labour, as in a case here reported when occasionally the umbilical cord lies below the foetal skull, the bleeding being then of ordinary decidual origin, and (3) if the head is displaced upwards by a myoma of the lower uterine segment or by a small extra-uterine pelvic tumour. In premature placental detachment the present writers had normal radiological findings with this method. The disadvantage of diagnosis by cystography is that it is only applicable when the head presents, cephalic version, however, is usually possible and has in several cases been done as a preliminary to the cystography.

## Pathology

483

#### Sulphur and Lactation

R. G. DAGGS and V. S. M. LIDFELDT (*J. Nutrit.* March 10, 1938, p. 211) have further examined the lactagogue effect of dietary proteins in rats. The effect is not lost on autolysing liver and is highest in the sulphur-containing fractions. Since inorganic sulphur compounds are inactive the lactagogue activity is attributed to sulphur-containing organic compounds. Assessing the lactogenic potency by weighing the litters the writers found that it is well shown by the sulphhydryl amino groups in cysteine, cystine or methionine. Simulated glutathione (a mixture of glycine and glutamic acid together with cystine or cysteine) is no more effective than cystine or cysteine, it is inferred that the S-H group is the essential factor although methionine containing sulphur in an SCH<sub>3</sub> form is equally effective and taurine (SO<sub>3</sub>H) has some

1248 F

lactogenic activity. The corresponding non sulphur amino acids are ineffective. That the increased growth in the young is due to the passage of cystine into the milk seems impossible, for administration to them of cystine gave negative results, and the milk of women given cystine contains S-H amounts not greater than that of controls. Increase of cystine in the rats' dietary led to fatty degeneration of the liver, which was preventable by the simultaneous administration of choline.

484

#### Actinomycosis

F. A. LENZL (*Zbl. Bakt.* 1938, 141, 21), who has been making a study of human actinomycosis, describes the finding in certain cases of an anaerobic diphtheroid bacillus differing in its morphological, cultural, biochemical, and serological behaviour from the classical *Actinomyces bovis* of Wolff and Israel. In these cases no granules could be found in the discharge. Films showed the presence of Gram-positive diphtheroid rods frequently arranged in pairs. Anaerobic cultivation for fourteen days yielded smooth circular, greyish-white colonies not adhering to the medium, yet containing bacilli similar to those found in typical adherent colonies of the Wolff-Israel type. For the sake of convenience the author refers to the new organism as the "S" form and to the Wolff-Israel type as the "R" form. Biochemically, both organisms fermented glucose and xylose within five days, the R form fermented salicin and the S form glycerol within thirty days, maltose, lactose, mannitol, and sucrose were fermented by the R form in a few days, but irregularly and usually only after a longer time by the S form. Antigenically three types were found among strains of the Wolff-Israel organism, while four strains of the new organism were very similar to each other. A slight degree of cross-agglutination between the S and R types occurred with some strains. As the result of experiments continued over five months one of the S forms was apparently transformed into the R type, though this observation needs to be confirmed. The exact relation of the two organisms to each other is still not clear, but the author seems to regard them as belonging to the same species.

485

#### Leptospira canicola

B. WALCH-SORGDRAGER and W. SCHULFINK (*Zbl. Bakt.* 1938, 141, 97) have made a careful study of *Leptospira canicola*. This organism, which is most easily differentiated from *L. icterohaemorrhagiae* by serological methods, gives rise to disease chiefly in the dog, in man only thirteen cases have so far been observed. The clinical picture in dogs infected with *L. canicola* differs from that in dogs infected with *L. icterohaemorrhagiae*. There is little or no jaundice, the kidneys are mainly infected, uraemia is common, the agglutination titre tends to be higher, the case mortality is lower, and the dogs that recover excrete leptospirae in the urine for weeks or months. In man jaundice is likewise lacking, the disease is milder than the typical Weil's disease, and meningeal symptoms are frequently observed. For the guinea-pig particularly on first isolation, *L. canicola* is much less fatal than *L. icterohaemorrhagiae*. After passage of the organism the virulence may increase. No jaundice is seen and in guinea-pigs that recover leptospirae may be excreted for months in the urine. Rats which serve as the international carrier for the Weil leptospirae are comparatively resistant to experimental infection with *L. canicola* and in spite of intensive search not a single wild rat caught has been found to be infected with this organism. From an epidemiological point of view dogs and not rats are the main carriers of *L. canicola*. Infection probably passes from dog to dog as the result of contamination of the tongue or nose with infected urine during the canine practice of sniffing the external genitalia of other dogs or of their urine after excretion. This probably explains why it is twice as common in dogs as in bitches.

*Out of the  
Shadow of Pain*

#### INDICATIONS—

Veganin has proved particularly serviceable in the treatment of headaches, migraine, rheumatic affections post-operative and post-puerperal pain in the backache and muscular pains of influenza

•  
Veganin Tablets are not advertised to the public

•  
Supplied in tubes of 10 and 20 boxes of 100, 500 and 1000 for dispensing

•  
A supply for clinical trial sent on request

WILLIAM R. WARNER  
& CO. LTD.  
POWELL ROAD CHISWICK  
LONDON W 4

## THE PATIENT'S INSISTENT NEED

Pain is the dominant symptom which induces the majority of patients to seek medical aid, hence the practitioner's reputation depends in no small degree upon his skill in relieving pain. For this he cannot have a more reliable ally than Veganin.

Veganin presents a synergistic combination of acetylsalicylic acid, phenacetin and codeine and is considered one of the safest analgesics. It is quickly absorbed and its action is prompt and prolonged.

Veganin affords effective relief in a vast number of painful conditions and alleviates the nervousness that so frequently accompanies them. There is no aftermath of languor and no systemic disturbance.

# Modern Iron Therapy

Iron Jelloids are an elegant and reliable means of administering the proto urbanic of iron. The preparation has none of the disadvantages of Pil Blaud. The iron content remains fresh and unoxidized indefinitely and

no injury to teeth is avoided. Iron Jelloids are highly effective in the treatment of achlorhydric anaemia and indeed in all the simple anaemias in which massive iron therapy is indicated.

# Iron Jelloids

You are cordially invited to apply for samples for clinical trial.

## TOXAEMIA

Many patients suffer from the metabolic and physiologic deficiencies which SALVITAE is designed to correct. They are virtually human septic tanks, their blood and tissues charged with poisonous products derived variously from the retarded wastes of catabolism from a chronically overloaded colon and other foci of infection.

# SALVITAE

SALVITAE takes care of the bowel stasis (and concurrent putrefaction or fermentation), the elimination of nitrogenous and toxic wastes from the kidneys and the neutralization of excessive acidity. With these major instigators of a toxic condition rendered inoperative, the patient must necessarily evince improvement.

## Keep HEART DISEASE in Mind

A wise physician has said—Of importance comparable to the diagnosis of cardiac disease is the recognition of its absence.

Your patients will appreciate your having a full knowledge of the condition of their hearts. There are few among them who would not welcome your suggestion that a thorough investigation be made, including an electrocardiographic examination.

You can do this now because the extremely accurate, thoroughly dependable, light weight, low priced VICTOR Electrocardiograph has

brought this valuable diagnostic medium within the reach of every physician. With the possibility of heart disease in mind, you can add electrocardiography that is accurate to the other diagnostic facilities that you now employ—and get the complete picture. So often would you use the electrocardiograph that your investment in it would be liquidated quickly.

See this entirely new and different precision instrument that you can use in your consulting room or at the bedside. Make a cardiogram on it, yourself. Sign and post the convenient coupon at once without obligation.

VICTOR X-RAY CORPORATION, LTD

## ST. ANDREW'S HOSPITAL FOR MENTAL DISORDERS NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY

President THE MOST HON THE MARQUESS OF EXETER CMG ADC

Medical Superintendent THOMAS TENNENT MD MRCP DPH DPM

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients who are suffering from incipient mental disorders or wish to prevent recurrent attacks of mental trouble, temporary patients and certified patients of both sexes are received for treatment. Careful clinical, biochemical, bacteriological and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

### WANTAGE HOUSE

This is a Reception Hospital in detached grounds with a separate entrance to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombic treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray room, an Ultra Violet Apparatus and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological and pathological research.

### MOULTON PARK

Two miles from the Main Hospital here are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit and vegetables are supplied to the Hospital from the farm gardens and orchards of Moulton Park. Occupation Therapy is a feature of this branch and patients are given every facility for occupying themselves in farming, gardening and fruit growing.

### BRYN-Y-NEUADD HALL

The seaside house of St. Andrew's Hospital is beautifully situated in a park of 330 acres. Llanfairfechan amidst the finest scenery in North Wales. On the North West side of the Estate, a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses and bowling greens. Ladies and gentlemen have their own gardens and facilities are provided for handicrafts such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton) who can be seen in London by appointment.

## COURT HALL, KENTON, near EXETER,

for the treatment of eight Ladies, voluntary, temporary, or certified patients.  
Large gardens and own dairy

CLIFFDEN TEIGNMOUTH for early and convalescent cases. A well appointed house with spacious balconies and extensive views of the South Devon coast. Sub-tropical gardens, own dairy in 25 acres. Private road to beach.

Resident Physicians: **BERTHA M. MILES MD BS** (Starcross 59)  
**ANNE S. MILES MRCS, LRCP** (Teignmouth 289)

## THE COPPICE, NOTTINGHAM

HOSPITAL FOR MENTAL DISEASES

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Occupational Therapy. Voluntary and Temporary Patients received.

Tel. 64117. For terms etc. apply to the Medical Superintendent.

## HAYDOCK LODGE

NEWTON-LE-WILLOWS LANCASHIRE

Teles. Street Ashton in Macclesfield

Phone Ashton in Macclesfield 7311

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES suffering from mental and nervous diseases either voluntarily, temporarily or under Certificate. Patients are classified in separate buildings according to their mental condition. Situated in park and grounds of 450 acres. Self-sufficient by its own farm and gardens in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus etc. apply MEDICAL SUPERINTENDENT.

## NORTHUMBERLAND HOUSE,

GREEN LANES, FINSBURY PARK, N4

A PRIVATE HOSPITAL for the treatment of mental and nervous illnesses. Conveniently situated and easy access from all parts. Six acres of ground, highly situated facing Finsbury Park. Voluntary and Temporary Patients received without certification. Occupational Therapy, Psychotherapy and other modern forms of treatment. Telephone STANFORD HILL 2655. Telegrams SUBSIDIARY LONDON. C. L. ASHLEY HOME, KILNNEY COURT, DOVER. For further particulars apply to the Medical Superintendent.

## STRETTON HOUSE, Church Stretton, Shropshire

A PRIVATE HOME for the treatment of Gentlemen suffering from Mental and Nervous Illness including the allied disorders of Alcoholism and the Drug Habit. All types of early Mental and Nervous cases are received without certificates as Voluntary Patients under the provisions of the Mental Treatment Act 1930. Bracing hill country. See Medical Directory p. 2125. Apply to the Medical Superintendent. Phone 10 P.O. Church Stretton.

## FENSTANTON, CHRISTCHURCH ROAD, Streatham Hill, SW2

A Private Home for the Care and Treatment of a limited number of Ladies with Mental and Nervous Disorders. Certified Voluntary and Temporary Patients received. Large Manion with 12 acres of grounds. (See Medical Directory p. 2312.) Apply Resident Physician. Telephone Tulse Hill 7181.

## BAILBROOK HOUSE, BATH

For sufferers from Nervous and Mental Disorders with or without certificates.

The house is gloriously situated in wooded grounds of 20 acres with magnificent views of the City and the Avon Valley. (See Medical Directory page 2322.)

For terms apply A. GUERIN M.A. D.M. B.Ch. D.P.M. Resident Physician. Telephone Bathaston 8159.

## HEIGHAM HALL, NORWICH

A PRIVATE MENTAL HOME situated in 11 acres of well wooded grounds. For Ladies and Gentlemen suffering from Nervous or Mental Illness. Voluntary Patients. Temporary Patients and Patients under Certificate are admitted for treatment. Fees from 4 guineas a week upwards according to requirements. A few vacancies exist for Ladies and Gentlemen at reduced fees on the recommendation of the Patient's own Physician. Apply to Dr. J. A. SMALL. Telephone 50 Norwich. Telegrams Small 80 Norwich.

## TYKEFORD-ABBEY, NEWPORT PAGNELL, BUCKS

FUNCTIONAL AND

The Home is a Mansion of Historical interest standing in 15 acres of garden and grounds and is situated 14 miles from Northampton and 12 miles from Bedford on the main London to Northampton Road, fifty miles from London. # HIS MAJESTY'S COLONIAL SERVICE

## COLONIAL MEDICAL SERVICE.

During 1938 the Secretary of State for the Colonies proposes to select a number of Medical Officers to fill vacancies the majority of which will occur in Tropical Africa and Malaya

**QUALIFICATIONS**—Candidates must be British subjects of European parentage under 35 years of age and must possess a medical qualification registrable in the United Kingdom. Preference will be given to candidates who have held Hospital or Public Health appointments or who have special knowledge of anaesthetics, radiology surgery medicine ophthalmology gynaecology and midwifery diseases of the ear nose and throat venereal diseases etc

**SALARY**—Initial salaries vary from £600 to £700 and rise by increments to a maximum of between £1 000 and £1 200

**PRIVATE PRACTICE**—Private practice is not allowed as of right but in the case of some appointments it is permitted on certain conditions

**QUARTERS**—In Tropical Africa free quarters or an allowance in lieu are provided. In Malaya quarters are provided at an annual rental not exceeding 6% of the officer's salary

**PASSAGES**—Free first-class passages are provided on first appointment and when proceeding on and returning from leave. Assistance is also given towards family passages

**TERMS OF APPOINTMENT**—The appointments are pensionable subject to a probationary period which varies from two to three years

**COURSES OF INSTRUCTION IN TROPICAL MEDICINE AND HYGIENE**—Selected candidates will normally be required to attend a course of instruction leading to the Diploma in Tropical Medicine and Hygiene before proceeding overseas

**DUTIES**—Although Medical Officers are appointed in the first instance for general service there are opportunities for work in special branches of medicine and surgery in public health, and in medical research

Further particulars and forms of application may be obtained from the Director of Recruitment (Colonial Service), 8, Buckingham Gate, London, S W 1

# ROYAL NAVAL MEDICAL SERVICE.

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in September, 1938

Candidates below the age of 28 years are preferred and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board

Selected candidates will be entered for Service for a period of three years, which if desired is usually extended to five years at the discretion of the Admiralty

At the end of three years' service officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000

At the end of five years' Short Service, permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax)

Full opportunities exist for transfer to the permanent list, and periods of unemployed or half pay are very rare. The assistance of private income is not necessary for the purpose of supplementing official pay and allowances

Opportunities are available for officers on the permanent list for post graduate study, to specialise, to take higher examinations and to obtain further qualifications

Naval Medical Officers are included in the Scheme for Marriage Allowance under the same conditions as for other Naval Officers

Copies of the regulations for entry and conditions of service, including rates of pay, allowances and retired pay may be obtained from the Medical Director General of the Navy, Admiralty, S W 1, and from the Deans of all Medical Schools

Applications for entry from intending candidates must be received not later than 31st August, 1938

**COUNTY BOROUGH OF SUNDERLAND**

**CHERRY KNOWLE**  
(Sunderland County Borough Mental Hospital)  
Ryhope near Sunderland

**APPOINTMENT OF  
MEDICAL SUPERINTENDENT**

Applications are invited from duly qualified and registered Medical Practitioners for the appointment of Medical Superintendent of Cherry Knowle. The salary will be £1000 per annum advancing subject to satisfactory service by annual increments of £50 to £1200 per annum plus emoluments valued for purposes of superannuation at £200 per annum.

In addition to the usual duties devolving upon him as Superintendent of Cherry Knowle the person appointed will be required to advise the Committee on all the mental health services of the Borough such as mental deficiency out-patient and after-care treatment and child guidance and to carry out the other duties set out in the terms and conditions of appointment.

At Cherry Knowle a general and diagnostic block and an early treatment block are being built and other improvements are being carried out. These will be completed next year when the accommodation of the Hospital will be for approximately 700 patients.

Form of application and particulars of the terms and conditions of appointment may be obtained from me and applications addressed to me and endorsed on cover Medical Superintendent Cherry Knowle together with copies of three recent testimonials must be delivered at my office not later than Friday June 10th next.

Canvassing either directly or indirectly until after the first selection of candidates by the Committee will be a disqualification.
